**Novel Treatment for Angina.**—Under the caption of "a natural protective influence against diphtheric and scarlatinal angina," Dr. Leopold Kürt (*Wiener Med. Woch.*, Nov. 2, 1901, p. 2054) makes a rather novel suggestion, based upon personal observation, with reference to the treatment of acute affections of the fauces and the pharynx. He believes that he succeeded in the case of himself in aborting a threatened attack of simple angina by frequent swallowing of saliva, and that he obtained great relief in an attack of faucial and pharyngeal diphtheria from the employment of the same expedient. From this experience he concludes that the secretions of the mouth may contain some substance naturally protective against diphtheria and other infections of the throat. During a period of five years that has elapsed since the observation, a considerable number of patients have been subjected to the treatment, and with most gratifying results. In order to stimulate the secretion of saliva, the use of sugar in some form convenient for gradual solution in the mouth is sanctioned. The useful influence of the saliva is attributed to the chemotactic action that it has been shown to exert, together with its mechanical effects. As an adjunct to this measure, the general use of water, in small amounts frequently, is encouraged. Further, it is, as a rule, desirable to favor cutaneous transpiration, by means of warm milk, with or without tea, particularly at a time when this takes place spontaneously. Pain attending the act of swallowing may be mitigated by pressing the hands against the ears. The method of treatment outlined in the foregoing is worthy of note on account of its novelty rather than for any particular merit it appears to possess, unless it be its innocuousness. There could be little objection to its institution in cases of simple angina, but in the presence of diphtheria, the employment of the antitoxin would render other measures of subordinate importance, and in cases of sore throat of other nature, the swallowing of the infectious material contained in the fauces and the pharynx might not be entirely free from danger.

**Encouragement from the Lay Press.**—Judging from its second annual report, the State Board of Registration in medicine is making it safer to live in Michigan and increasing the average life of her citizens. She has ceased to offer an open field to the quack and the board is doing all within its power to establish such a standard of medical qualification as will insure the highest attainable degree of safety. It has accomplished much by heading off those within the state who had been practicing without more than a bowing acquaintance with their noble profession, and has erected protective barriers against the graduates of "fake" medical schools. The man who has credentials from these swindling institutions alone must find a market for his false pretenses outside of Michigan or seek some more reputable employment in which his opportunities for mistakes do not include those of killing his fellows.

This is much to have accomplished in so brief a time and upholds the adoption of such a branch of the service. But there is more to be done. The work will not be perfected so long as there remains a single sanction of law under which any man or woman can be a practitioner in this state unless he or she can meet the highest requirements that equitable legislation can fix. It is not enough to provide against an influx of outside charlatans. We have enough medical institutions in Michigan to more than meet the demand for doctors and the inevitable tendency is to encourage the turning loose of incompetents. It is because of this that the *Free Press* has favored an authorization of the Board to examine students as to their preliminary education before they begin a prescribed medical course. This does not preclude acceptance of the fact that there may be an occasional doctor born, just as there is a poet, artist or inventor, but he is such a rare avian that it is not permissible to consider him as a vital factor in dealing with a profession that aims to stand off death where it is within the range of human possibility to do so. Ninety-nine persons out of a hundred who have not laid an educational foundation are disqualified and public safety demands that they all be barred, for attempted discrimination would only be less dangerous than an open door. The law will do what is wanted by those behind it, when it licenses only those who are best fitted to practice.—*Detroit Free Press*, Jan. 10, 1902.

**The Bactericidal Power of Certain Urinary Disinfectants.** Bacteria may gain entrance into the urinary passages either directly through continuity of structure, or indirectly through the blood-stream; and by some it is held that infection may take place, also through contiguity of structure, by way of the lymphatics. In any event, it was extremely desirable to be in possession of means for preventing such a contingency, or for combating it should it arise. It is true a number of medicaments have been recommended for this purpose, but of most of them it must be admitted that although they may exhibit marked bactericidal activity in the test tube they can not safely be administered in doses sufficiently large to bring about the desired results, or that they become so changed in the body when administered internally as equally to fail of their purpose. Appreciating these facts Dr. Arnold Wanner (*Centralblatt f. d. Krankheiten der Harn- und Sexual-Organen*, B., xii, No. 11, p. 293) undertook an experimental investigation for the purpose of determining the bactericidal powers of a number of drugs that have been recommended as urinary antiseptics. He administered the drugs in question to healthy individuals, and the urine passed on the succeeding night was collected in sterile vessels. This urine was then inoculated with bouillon cultures of the respective microorganisms and put aside in the thermostat for observation and comparison with control uninoculated specimens. As a result of this study it was found that boric acid, guaiacol and cresolate, when administered internally, even in large doses, exert no influence upon the development of bacteria in the urine. Benzoic acid in small doses (9 grains daily) likewise exhibits no such action, but when given in larger doses (from 15 to 90 grains in the day) the growth of streptococcus pyogenes is inhibited, while other bacteria are on the other hand not affected. The growth of streptococcus is not inhibited by salol, while that of staphylococcus albus and proteus is retarded distinctly, and that of bacterium coli and bacillus typhi and staphylococcus aureus is not materially affected. After the internal administration of metoprin this substance can always be found in the urine within a short time. Likewise formaldehyd can always be found in acid urine and the reaction is the more distinct the more pronounced the acidity of the urine. The growth of bacteria is almost entirely prevented, although bacterium coli exhibits sluggish growth even in urine containing formaldehyd. At first this failure of growth depends only upon inhibition, while the bacteria retain their viability. After prolonged action of the formaldehyd, however, actual destruction of the bacteria takes place. Here again the bacterium coli is the most resistant of the organisms. Tannepin and tannoform exhibit no influence upon the development of bacteria in the urine.

## Societies.

**FRESNO COUNTY (CAL.) MEDICAL SOCIETY.**—This Society met at the County Hospital, Fresno, January 7, elected Dr. Warren T. Harr, President, and re-elected Dr. Cowan, secretary, both of Fresno.

**CHARLESTON (W. VA.) MEDICAL ASSOCIATION.**—At the annual meeting of the Society January 7, Dr. William W. Tompkins was elected president, Dr. James Putney, vice-president, Dr. Charles O. Grady, secretary, and Dr. John L. Stump, treasurer.

**MEDICAL SOCIETY OF THE STATE OF NEW YORK.**—This Society will hold its next annual meeting in Albany January 28, 29 and 30. The program contains a list of 51 titles. The president is Dr. Henry S. Elmer, Syracuse, and the secretary, Dr. F. C. Curtis.

**LA CROSSE COUNTY (WIS.) MEDICAL SOCIETY.**—At the annual meeting of this Society at La Crosse, January 7, Dr. Charles H. Marquardt was elected president; Dr. John A. L. Bradfield, vice-president, and Dr. Edward Lynda, secretary and treasurer, all of La Crosse.

**CLINTON COUNTY (OWAS) MEDICAL SOCIETY.**—At the annual meeting of this Society, held in Clinton, January 7, Dr. Edward L. Martindale was elected president; Dr. Harry R. Reynolds, vice-president, and Dr. F. A. Hohenachuh, secretary and treasurer, all of Clinton.

**HOUSTON (TEX.) DISTRICT MEDICAL ASSOCIATION.**—At its regular meeting in Houston, January 13, this Association elected Dr. Zachariah F. Lillard, Houston, president; Dr. Edward M. Arnsstrong, Houston, vice-president, and Dr. E. J. Hamilton, secretary and treasurer.

**HUNTINGTON (W. VA.) MEDICAL SOCIETY.**—The annual meeting and election of this Society were held January 9. Dr. Henry A. Brandburg was elected president; Dr. Morgan Baker, vice-president; Dr. Thomas W. Moore, secretary, and Dr. George M. Waldeck, treasurer.

**JACKSON COUNTY (MICH.) MEDICAL SOCIETY.**—This Society held its annual election, meeting and banquet, January 14. Dr. Albert E. Rubson was elected president; Dr. Martha C. Strong, vice-president; Dr. R. Grace Hendrick, secretary, and Dr. Frederick W. Rogers, treasurer.

**JOHNSON COUNTY (OWAS) MEDICAL SOCIETY.**—The annual meeting of this organization was held in Iowa City, January 7. Dr. John G. Mueller was elected president; Dr. William R. Whitels, vice-president, and Dr. L. Clark Mighell, secretary and treasurer, all of Iowa City.

**LUCAS COUNTY (OHIO) MEDICAL SOCIETY.**—At the last meeting of this Society in Toledo, Dr. William D. Stewart was elected president; Dr. Parks L. Meyers, vice-president; Dr. Francis W. Alter, secretary; Dr. Herbert E. Smed, financial secretary, and Dr. John A. Wright, treasurer, all of Toledo.

**RAYMONNE (N. J.) MEDICAL SOCIETY.**—This Society, which held its meeting for organization in October last, is flourishing and reports a membership of 19 with the following officers: Dr. Fred M. Corwin, president; Dr. Archibald C. Forman, vice-president, and Dr. P. C. Stevens, secretary and treasurer.

**HARTFORD (CONN.) MEDICAL SOCIETY.**—At the annual meeting of the Society January 6, Dr. Nathan Mayer was elected president; Dr. William T. Bacon, vice-president; Dr. Joseph E. Root, secretary; Dr. George N. Bell, assistant secretary; Dr. George K. Welch, treasurer, and Dr. Frederick T. Simpson, librarian.

**JACKSON COUNTY (CAL.) MEDICAL SOCIETY.**—This Society held its annual meeting at Scottsboro, January 7, and elected Dr. Walter C. Sanders, Stevenson, president; Dr. Thomas E. Callan, Eacker, vice-president; Dr. James P. Rorex, Scottsboro, secretary and treasurer, and Dr. John Boggess, Woodville, county health officer.

**JUVAL COUNTY (FLA.) MEDICAL SOCIETY.**—This Society held its annual meeting at Jacksonville, January 7. Dr. James D. Love was elected president; Dr. Charles B. Spratt, vice-president; Dr. Jay H. Durkee, secretary and treasurer; Dr. Percy J. Stollenwerck, corresponding secretary, and Richard P. Daniel, permanent honorary president, all of Jacksonville.

**TOLEDO (OHIO) MEDICAL ASSOCIATION.**—At the annual meeting held January 10, the following officers were elected: President, Dr. John North, vice-president, Dr. Albert E. McVety; recording secretary, Dr. Charles P. Wagar; corresponding secretary, Dr. August C. Schmetzler, and treasurer, Dr. Frank E. Klausner. The Society then banqueted at the St. Charles Hotel.

**MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA.**—At the annual meeting of this Society, held January 4, the following officers were elected: President, Dr. Samuel S. Adams; vice-presidents, Drs. John W. Chappel and Aurelius R. Shands; recording secretary, Dr. F. P. Morgan; corresponding secretary, Dr. Thomas C. Smith; treasurer, Dr. Charles W. Franzoni, and librarian, Dr. E. L. Morgan.

**ASHTABULA, LAKE AND GEALGA COUNTIES (OHIO) MEDICAL SOCIETY.**—At the meeting of this tri-county Society at Ashtabula, January 7, the following officers were elected: Dr. Bryant M. Tower, Conneaut, president; Drs. William I. Gilchrist and Addison W. Hopkin, both of Ashtabula, vice-presidents; Dr. William S. King, Ashtabula, treasurer, and Dr. Ernest Crockett, Dorset, secretary.

**BRIDGEPORT (CONN.) MEDICAL ASSOCIATION.**—The thirtieth annual meeting and banquet of this Association were held January 4. Dr. George R. Cowell, retiring president, was the toastmaster. The following officers were elected: Dr. Frank M. Tukey, president; Dr. Fessenden L. Day, vice-president; Dr. George S. Ford, secretary; Dr. James G. Gold, treasurer, and Dr. Herbert E. Smyth, curator and librarian.

**CAMDEN (N. J.) CITY MEDICAL SOCIETY.**—At the annual meeting of this Society January 7, a resolution was adopted urging immediate opening of public schools to successfully-vaccinated children. The following officers were elected: Dr. Robert Casperson, presi-

dent; Dr. John F. Leavitt, vice-president; Dr. Vernon E. De Grofft, secretary; Dr. William H. Pratt, treasurer; Dr. Daniel Strook, historian, and Dr. Joseph H. Willis, librarian.

**BUNCOMBE COUNTY (N. C.) MEDICAL SOCIETY.**—The annual meeting of this Society was held January 6, at Asheville, when Dr. S. Westray Battle was elected president; Dr. Charles S. Jordan, vice-president; Dr. Galliard S. Tennent, secretary; Dr. Carl V. Reynolds, treasurer; Dr. John H. Woodcock, corresponding secretary, and Dr. Frank T. Meriwether, member of Board of Control, all of Asheville. The meeting was followed by a banquet at the Swannanoa.

**ANDROSCOGGIN COUNTY (MAINE) MEDICAL ASSOCIATION.**—The annual meeting and banquet of this Society were held in Lewiston, January 7. The banquet was given by Dr. Oliver F. Sprague, Turner, the retiring president. The following officers were elected: Dr. Wallace Oakes, Auburn, president; Dr. Milton C. Wedgewood, Lewiston, vice-president; Dr. Edgar F. Conant, Lewiston, secretary; Dr. Benjamin G. W. Cushman, Auburn, corresponding secretary, and Dr. Benjamin F. Sturges, Auburn, treasurer.

**ST. JOSEPH (MO.) MEDICAL SOCIETY.**—This Society held its first meeting of the new year January 14, with an attendance of forty. Dr. J. M. Bell read an interesting paper on "Glycosuria." A committee on re-organization and incorporation was appointed, with a view to affiliation with the State and the American Medical Associations. The election of officers resulted as follows: President, Dr. Thompson E. Potter; vice-president, Dr. Charles H. Wallace; secretary, Dr. John M. Bell, and treasurer, Dr. Charles Wood Fassett.

**THE WYOMING COUNTY (N. Y.) MEDICAL ASSOCIATION.**—The semi-annual meeting of this Association was held at the Castle Sanitarium, Castile, N. Y., January 14. The meeting was called to order at 10:30 a. m., when the following program was presented: "Remarks on Leprosy," J. E. Walker; "The Function of the Periosteum in the Regeneration of Bone," Dr. A. G. Ellewoud; "Alopecia," with cases, Dr. Mary Slade; "Glimpses of Medical Work in Leone Korea," Dr. Rosetta Hall, and "Apoplexy," with cases, Dr. C. C. Mann.

**FREDERICK COUNTY (MD.) MEDICAL SOCIETY.**—The following officers were elected at the annual meeting of this Society, held in Frederick, January 10: Dr. Samuel T. Haffner, Frederick, president; Drs. Franklin B. Smith, Frederick, and Richard W. Trapnell, Point of Rocks, vice-presidents; Dr. Ira J. McCurdy, Frederick, recording secretary; Dr. William C. Johnson, Frederick, treasurer, and Dr. Joseph E. Beatty, Middletown, librarian. A resolution was adopted forbidding any member from having any official relations with any hospital with which an irregular is connected.

**ACHISON COUNTY (MO.) MEDICAL ASSOCIATION.**—This Association organized January 7, at Rockport, with 14 members. John A. Postlewait, Tarkio, was elected president; Dr. Austin McMichael, Rockport, secretary, and Dr. James A. Hunter, Fairfax, treasurer. Dr. E. E. Richards, Tarkio, presented a paper on "Pneumonia," and Dr. George W. Lott, Westboro, one on "Diphtheria." The latter paper was followed by a lively discussion on the identity or non-identity of diphtheria and membranous croup. The next meeting is to be held April 9, in Fairfax.

**COLES COUNTY (ILL.) MEDICAL SOCIETY.**—This Society held its first annual session January 13, at Charleston, and elected the following officers: Dr. Lemuel L. Silverthorn, president; Dr. William H. Lyan, vice-president, and Dr. John H. Bush, secretary and treasurer, all of Charleston. The Society includes in its membership all the physicians of Charleston and a few located in the smaller towns in Coles County. Its aim is to eventually include all physicians in the county, to have a uniform fee-bill, to locate the dead-beats, to get better pay and to enforce the city ordinance against street vendors.

**PRINCE GEORGE'S COUNTY (MD.) MEDICAL ASSOCIATION.**—This Association met at Hyattsville, January 8, and appointed a committee to urge upon the State Legislature the passage of a bill to permit physicians residing in the District of Columbia to practice in Maryland, provided they are registered in the District, by presenting proof thereof to the Medical Examining Board of Maryland, accompanied by a certificate of the Examining Board of the District of Columbia, that they are in good standing. Drs. Wells, Griffith, Fox, Fowler, Gibbins and Ryan were appointed a committee to urge the bill.

**BALTIMORE MEDICAL AND SURGICAL ASSOCIATION.**—At the annual meeting of this Association, January 13, the following officers were elected: Dr. J. Lowrey Ingle, president; Drs. John W. C. Chambers and Randolph Winslow, vice-presidents; Dr. Eugene L. Crutchfield, secretary; Dr. Martin B. Billingslea, treasurer; Drs. Charles G. Hill, William S. Love and W. B. Wolf, executive committee, and Drs. Hampson H. Biedler, G. Lane Taneyhill and James M. H. Rowland, committee of honor. At the conclusion of the meeting the members sat down to the annual banquet, at which Dr. John Parkinson, Logan, committee on admissions.

**WEBER COUNTY (UTAH) ACADEMY OF MEDICINE.**—The Academy, at its annual meeting held in Ogden, January 9, elected Dr. James X. Allen, Ogden, president; Dr. John S. Gordon, Ogden, vice-president; Dr. John Driver, Ogden, secretary; Dr. Samuel L. Brick, Ogden, treasurer; Dr. George W. Perkins, Ogden, librarian; Drs. John Driver, Samuel L. Brick, Ogden, and Ephraim Gowans, executive committee; Drs. George W. Perkins, James X. Allen, Ogden, and Charles F. Osgood, Morgan, committee on medical ethics, and Drs. George W. Baker, John S. Gordon, Ogden, and William B. Parkinson, Logan, committee on admission.

**CLEVELAND (OHIO) MEDICAL SOCIETY.**—This Society held its tenth annual meeting January 10. Dr. Frank Winders, Columbus, secretary of the State Board of Registration and Examination, read a paper on "Medical Legislation," in which he stated that the number of illegal practitioners in the state was due to the refusal of prosecuting attorneys to carry out existing laws. The following officers were elected: Dr. P. Maxwell Foshay, president; Drs. John H. Belt and George D. Upson, vice-presidents; Dr. Walter H. Merriam, recording secretary; Dr. John M. Ingersoll, treasurer, and Dr. Robert G. Schnee, pathologist.

**MARION COUNTY (OHIO) MEDICAL SOCIETY.**—At the annual meeting of this Society, held at Marion, January 7, Dr. Oliver W. Weeks was elected president; Dr. Robert Ramroth, vice-president; Dr. Herman S. Rhu, secretary; Dr. Ambrose Ogan, treasurer; Drs.

Lewis D. Hamilton, Horatio Chisholm and A. Melville Crane, standing committee, all of Marion. An amendment to the Constitution of the Society was submitted making all legal practitioners of medicine and surgery eligible to membership, who have conformed or hereafter may conform to the laws regulating the practice of medicine and surgery in Ohio. The article of the Constitution sought to be amended provides only for the admission of regulars.

**CINCINNATI SOCIETY FOR MEDICAL RESEARCH.**—A meeting of this Society was held in the laboratory of the Cincinnati Hospital, January 9. Dr. Albert H. Freiberg read a paper on the structure of bone from the viewpoint of comparative anatomy. Illustrated by radiograph lantern slides from sections of the femurs of man, baboon, leopard, sheep, ox, and llama to show the relation of function to structure in these bones. The demonstration was in the nature of a preliminary communication. He also exhibited the right os-innominate and both femora from a case of old unreduced traumatic luxation of the right hip, the specimen being taken from the museum of the Cincinnati Hospital. The luxation had existed for a sufficiently long time, and the limb had been so much used that a new rudimentary acetabulum had been formed. Radiographs of sections from the femora were shown to illustrate the changes in internal architecture and external configuration which had taken place solely as the results of changed static conditions. It was held that these changes were in conformity with the requirements of Wolff's "Gesetz der Transformation." Dr. Meyer L. Heidsieckfeld demonstrated the nature of plasma cells and briefly stated the views maintained by different authorities on this interesting subject. He endeavored to show that Unna was probably correct in the views that he holds for his plasma cells, which stain without nuclei with his polychrome-methylene blue, and are similar morphologically, and in color reaction to connective tissue cells, from which they take their origin. The Marschalko cells, on the other hand, stain with Unna's polychrome-methylene blue with nuclei, and are morphologically and in staining properties similar to lymphocytes, from which they take their origin. Dr. Friedlander dissented from this view, and was of the opinion that inasmuch as Unna's polychrome-methylene blue was a nuclear stain, a nucleus must be demonstrable in the plasma cells of Unna.

#### NORTH BRANCH OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Meeting, held December 20, 1901.*

The meeting was called to order by the Temporary Chairman, Dr. H. Booker Mills, who introduced Dr. Jay. F. Schamberg; the latter read a paper on "The Differential Diagnosis of Variola, Varioloid and Varicella." The paper is published in full in this issue, page 215.

"Vaccine Virus, Its Preparation and the Accidents Following Its Use" was the title of a paper read by Dr. Joseph McFarland, which is also published in full on page 217.

#### Recent Vaccinations—Old Scars—Complications of Vaccinations.

DR. WILLIAM M. WELCH, read a paper entitled: 1, Deductions from Studies of Recent Vaccinations; 2, Interpretation of Old Scars; 3, Complications of Vaccination. The Doctor commented on the fact that not a single person has been admitted to the Municipal Hospital suffering with smallpox, during the present epidemic in this city, who had recently been successfully vaccinated. He estimates that since the outbreak of this disease at last 500,000 people have been vaccinated in this city, and although 800 cases of smallpox have been admitted to the hospital not one of this 500,000 has been among the number. As a positive proof of the efficacy of recent vaccinations the Doctor mentioned several instances in which recently vaccinated individuals have been exposed to this disease continuously for several weeks and remained immune therefrom. Notably among these is the case of a child one year old who was sent to the hospital supposed to be suffering from variola, but who was actually affected with roseola vaccinosa, having been successfully vaccinated about ten days previously. This child remained in the smallpox wards for about three weeks and continued perfectly well. Several other similar cases have occurred in this institution, in all of which the outcome has been the same.

In every epidemic of smallpox which has occurred in this city within the past thirty years—all of which the Doctor has observed personally—whole families have been removed to the hospital because of an outbreak of this disease in the household and not in a single instance has the disease been contracted by a recently vaccinated child, even although they were constantly exposed to the disease for several weeks, living, eating and sleeping in the infected atmosphere, and in all this period there has not been brought to his notice the case of a single unvaccinated child who escaped contagion under similar circumstances.

As a further evidence of the value of vaccination mention was made of the frequent observation of cases in which vaccinated infants have been nourished at the breast of a mother suffering from varioloid, which children remained as free from smallpox as if the disease was a hundred miles away, and the food derived from the most wholesome source.

Another striking illustration of the prophylactic value of vaccination is the case of a family composed of a father, mother and six children who were recently admitted to the hospital. Two of the children had arrived at the school age and had been successfully vaccinated and both of them remained entirely free from the disease, notwithstanding the fact that they were continually in contact with the sources of contagion; the four younger children who had never been vaccinated, all had unmodified smallpox; and the father and mother, who had not been vaccinated since infancy, both suffered from mild attacks of varioloid. Numerous cases have occurred in which the older children who had arrived at the school age and were therefore compelled to be vaccinated before they could be admitted, have remained at home entirely free from the disease, while the younger children, being unprotected, were sent to the hospital suffering from the most virulent forms of the disease.

In the alterations at the Municipal Hospital made necessary by the unusually large number of patients sent there during the recent epidemic of smallpox, from 50 to 60 men were employed. As they were compelled to come in close proximity to the disease in their work, all were recommended to get vaccinated, which suggestion was acted upon by all but two, both of whom contracted smallpox.

Of the 50 persons who have been continuously exposed to smallpox in the hospital during the present epidemic, in the capacity of physicians, nurses, ward maids, cooks, laundresses and the like, not one has contracted the disease and all of these persons, with the exception of two or three, owe their immunity to vaccination. Previous to assigning them to duty each person is carefully vaccinated, even although the vaccination of infancy and a subsequent vaccination show evidence of having been successful, and attention was called to the fact that, with this precaution, the author had never seen a resident physician or nurse take smallpox.

#### The Technique, Value and Object of Vaccination.

DR. JUDSON DALAND emphasized the importance of proper cleansing of the skin prior to vaccination. He considers it best, if the patient be a female, to vaccinate upon the antero-external aspect of the lower fifth of the thigh; if a right-handed male, the operation should be performed upon the antero-internal portion of the middle third of the left arm. He recommends thorough cleansing of the skin with hot water and white castile soap, after which that portion of the skin to be vaccinated should be rubbed with a sterile towel dipped in the soap and water until the upper layers of the skin have been rubbed away, and a diffused redness showing that the capillaries have been almost ruptured can be seen. This portion of the skin should then be rendered surgically clean by the free use of alcohol followed by ether. A sterilized steel, five pointed scarificator should be drawn parallel with the long axis of the limb and the scratching continued until there appears over a surface about one-fourth inch in diameter a moisture composed of serum slightly blood-tinged, after which the scarificator should be moved at right angles until the wound presents a uniform pink appearance due to the slight exudate of blood stained serum. The virus should then be applied and brought into thorough and intimate contact with the abraded surface by means of the scarificator, after which one of the ordinary shields should be applied, which the patient should be instructed to remove in about 12 hours, within which time, under ordinary circumstances, a sufficient scab will form to prevent re-infection of the wound from the skin or outside. The wound should be further protected by a simple surgical dressing, which should be removed, the wound cleansed and a fresh dressing applied nightly. So soon as the first evidence of inflammation shows itself, the physician should carefully cleanse the point of vaccination and surrounding skin with

abundance of sterile hot water and white castile soap, and after thorough drying, the surrounding parts should be thoroughly cleansed with alcohol, care being taken not to disturb the scab. The surrounding skin should be rubbed with simple oxid of zinc ointment, or better still, with an ointment composed of five grains of boric acid to the dram of lanolin and almond oil.

A surgical dressing composed of a thin piece of lint covered with this ointment should be applied to the pustule, over which should be placed a thin layer of borated absorbent cotton, these being held in place by a roller bandage. This local treatment should be repeated once, twice or thrice daily depending upon the amount of suppuration. The repeated cleansing and dressing of the wound prevents infection of the surrounding skin and the consequent danger of its transmission to the wound, and it also avoids pus accumulating and causing sepsis.

Attention was directed to the observations made during the past two centuries, practically all of which tend to show that vaccination when properly performed and under proper circumstances renders most individuals immune to variola, and when such an individual acquires smallpox poison varioloid is produced which is usually a mild affection, in which pitting of the face seldom occurs and the mortality rate following is very low. Attention was directed to the fact that it must not be overlooked, however, that an unvaccinated person who is brought into contact with varioloid may develop smallpox.

In the opinion of the author those vaccinated not only escape smallpox, but many do not even take varioloid even when exposed to smallpox poisons, unless the quantity of the poison received be considerable, and this opinion is also held by many other eminent observers and corroborated by statistics gathered from all parts of the world, notably among which are the observations made by Dr. Koch during an epidemic of this disease in Germany, which showed the mortality rate among the unvaccinated to be 32 per cent., while that of the vaccinated was only 9.5 per cent., and in this single epidemic alone more than 2000 lives would have been saved had these people enjoyed the protective influences of vaccination.

#### Tetanus Following Vaccination.

DR. WILLIAM I. KEICHNER of Camden, N. J., dealt freely with the symptomatology and treatment of a case of this character which has recently been under his care. There was but a very short period of incubation and the Doctor was inclined to look upon this complication as being caused by some micro-organism present in the virus used in vaccinating the patient. All the typical symptoms of this disease were present, there was convulsive twitching of the muscles, and the temperature at one time rose as high as 105 F. Tetanus antitoxin was injected in the early stage of the disease, and it is to the prompt use of this remedy that the Doctor attributes the recovery of the patient, who is now convalescing; strychnia was also administered hypodermically in large doses. The author felt that with care in the preparation of vaccine, virus could be produced which would be free from these micro-organisms, and he expressed the belief that in order to be of any use in cases of tetanus, the antitoxin must be given very soon after the onset of the condition.

DR. WILLIAM F. EIGIN, a physician who has had large experience in the manufacture of vaccine virus, opened the discussion. He referred to the fact that many physicians think that because a person is successfully vaccinated and then one or two years later is again vaccinated and it takes, that that person would contract smallpox, if exposed to the disease. This he believes to be an error and cites in support of his opinion the fact that he has had under his observation for the last two years about 200 or 300 young people employed in the manufacture of this virus, and has observed that when a party comes to work in the laboratory that has not been successfully vaccinated since childhood, they immediately vaccinate themselves in any abrasion that may occur on the fingers, on the hands or even on the face, sometimes having one, two or three or even more vesicles to the finger, which is often followed

by a re-vaccination in the same manner in two or three weeks afterward, and he has observed instances where the same party would again vaccinate themselves for the third time within twelve months. In his opinion in order to secure protection against subsequent vaccination, it would be necessary to vaccinate to the point of saturation, and while he does not doubt that this point can be reached, yet he feels that it is very rarely attained by the methods practiced in this country. He referred to the recommendations contained in the circulars sent out to the vaccine physicians in that country by the English government, which insist that there should be four insertions, which must equal in the aggregate one-half square inch of surface, claiming that better protection is secured by this method.

Referring to the statement previously made regarding the longer duration of immunity from human virus, he remarked the fact that Mexico was one of the most poorly vaccinated countries in the world, and in England, where they are using human virus for vaccination at the present time, they are having the same trouble with smallpox following vaccination as was experienced in this country some years ago.

He states that the animals used in the preparation of this virus are especially selected and especially tested in order to make sure that no infectious disease and especially tuberculosis is present. After this the animal is carefully washed in strong alkaline soap solution, then the hair is shaved from the abdominal region, and the animal is again thoroughly washed with soap and water, followed by bichlorid solution, and then rubbed hard with towels sterilized under 15 pounds pressure in the steam chest. The animal is then inoculated with the serum, the ordinary scalpel being used and a single scarification made. Great care is taken never to draw a drop of blood, which the speaker believes to be inadvisable in vaccinating, claiming that as soon as you have gotten through the superficial epidermis you have gotten far enough, whereas, on the other hand, he thinks that many of the complications of vaccination are due to this cause, his theory being that when the micro-organisms on the surface of the skin are carried into the subcutaneous layers of the skin, these pathogenic conditions are likely to occur. The glycerinized virus is considered by this speaker to be far preferable to the dry points, as he has observed several cases in calves vaccinated with the dry points (which was the method formerly used in the laboratory under his observation) where the odor from the wound became very offensive and the amount of discharge very great in three or four days, whereas these conditions have never been observed in an animal vaccinated with the glycerinized virus.

DR. ROBERT N. WILLSON referred to two cases of tetanus following vaccination which had recently come under his observation, both of which terminated fatally, one in 30 hours and the other in six days after the development of this condition. Both of these cases had passed through a long incubation period; in the former tetanus developed in 28 days and in the latter 21 days after vaccination; both were children of stablemen and both families lived in close proximity to the stables, one of them sleeping with its father, who was a coachman. Both of the children were vaccinated in the most aseptic manner, the arm being carefully sterilized prior to the operation, but no after precaution was taken, excepting that the wound was dressed with a shield. Both ran a course of typical vaccinia before the development of tetanus. The speaker stated that the case referred to by Dr. Kelchner in his remarks was the only case of tetanus following vaccination he had ever heard of that was not preceded by a long incubation period. Both of these cases were treated with tetanus antitoxin, the remedy being administered before any convulsive symptoms appeared, and the fact that both cases proved fatal, as well as other observations he has made, leads the Doctor to believe that antitoxin has very little value as a curative agent in tetanus, its use being rather to make the patient immune from the disease, in which capacity he believes it is invaluable. In regard to the source of the infection, the Doctor believes that we should be sure that the wound has been cared for aseptically before we can attribute it to the virus. During the past

three weeks Dr. Willson and another physician have been attending to the vaccination of the students at the University of Pennsylvania and out of the 3000 men in that institution there was but one man who had not been successfully vaccinated some time in his life, and there was only one case of smallpox, which occurred in a man who had not been vaccinated since early childhood. In all about 560 of the students were vaccinated, the same virus being used as was used to vaccinate the children previously referred to who died of tetanus, the wounds were aseptically treated and there was not a single occurrence of this complication.

DR. C. P. FRANKLIN considers that many of the complications following vaccination are due to shields and is at present following out an original idea of always putting on the vaccination, as soon as the virus is placed thereon, a little piece, say three-eighths of an inch square, of silk surgical plaster, aseptized and prepared as would regularly be done for other surgical uses. He then puts on a dome-shaped aluminum shield, which is also an original idea, the dome being formed by two ribs of the metal. This serves to protect the arm from the heavy winter underclothing and from inadvertent scratching, particularly by children. He has been using this method for some time and has since had no cases of tetanus and very few cases of inflammatory conditions of the arm.

DR. HUGH HANNA referred to a case of tetanus that followed vaccination which had recently come under his observation. This case occurred in a child and the symptoms of this complication developed about 16 to 18 days after the vaccination. The sanitary conditions were far from ideal, as the house was directly connected with a stable, the door from the dining-room opening into the stable, and the Doctor is of the opinion that this, together with the fact that people were not very careful in their habits, is quite likely to be responsible for the infection. The child was vaccinated on the left thigh. All the typical symptoms of tetanus were present, the lockjaw lasted about a week, opisthotonos was pronounced and the convulsions of the muscles would come on at any time, day or night. No antitoxins or other injections were used, but potassium bromid was administered in 20 to 30 grain doses every hour for four or five hours, when it began to produce its effect, after which it was given on a two-hour basis. There was a small quantity of tincture of opium used in the early stages, but this discontinued after the first day or two. After the severity of the spasm was relieved; it was observed that the stomach did not seem inclined to tolerate the bromid much longer and other narcotics were then resorted to. This was just prior to the beginning of convalescence. In about three weeks after the onset of the attack the child was able to sit up in bed and be helped up and sit in a chair, and now, several weeks later, she is able to go about the house. Her convalescence has been rapid.

#### THE CHICAGO MEDICAL SOCIETY AND THE CHICAGO SOCIETY OF INTERNAL MEDICINE.

*Joint Meeting, held Nov. 27, 1901.*

Dr. Edward F. Wells, in the Chair.

DR. EDWARD F. WELLS delivered the Presidential Address of the Chicago Society of Internal Medicine. He selected for his subject "The Consideration of Some Important Subjects Connected with the Treatment of Pneumonia." This address was given in full on page 163 of last week's issue.

#### Four Cases of Pleurisy with More or Less Permanent Pneumonic Induration.

DR. ROBERT H. BARCOCK followed with this paper and propounded the query: Are they tuberculous? Within the last three years he has observed four cases of pulmonary disease which were to him unusual and whose pathology it was difficult for him to explain on any other hypothesis than that they were tuberculous.

CASE I.—In April, 1898, a young man, about 20 years of age, was brought to his office by the attending physician because of pleuritis. About three weeks before he had complained of

pain in the right side, chilliness, cough, and malaise. He was found to have a temperature of about 101 F., and to present signs of right-sided pleurisy. Examination showed slight increase in the diameter of the right thorax, the apex beat displaced to the left nipple and the liver palpable. Pectoral fremitus was increased over the right upper lobe, but diminished below and practically absent at the posterior base. Over the right apex there were marked dullness and bronchial breathing, but no râles, as far as the third rib in front and behind to just below the ridge of the scapula. Below this level the percussion note was flat, bronchial respiration was feeble, but not absent, and there were no râles. The case was pronounced one of pleurisy with effusion, probably tuberculous, with pneumonia of the upper lobe. As three weeks had elapsed without absorption, and his temperature was still elevated, about 101 F., the author advised rest in bed and aspiration. Aspiration was done a few days later, and 20 ounces of clear straw-colored serum were obtained. Meanwhile his scanty mucous sputum had been examined for tubercle bacilli, but none discovered. After the tapping, the physical signs did not change in the least, dullness and bronchial breathing remaining just as pronounced as before. Even the position of the apex beat did not alter appreciably. In short, the patient's pulmonary and general condition persisted in *statu quo*. He was kept in bed in spite of his declarations that he felt so well he wanted to get up and did not see why he was confined to his bed. At the end of another week or ten days the attending physician, not satisfied with aspiration, called in a surgeon to aspirate again, which he did, with the result of withdrawing only about 6 ounces of serum. The lung findings remained as before, and the constitutional symptoms persisted. He did not see the patient again that year, but learned that he gradually improved, and after some weeks was able, or rather was permitted, to resume his former active habits, although his lung did not clear up. The following summer, more than a year subsequent to the author's first examination, patient consulted him again at his request. He found the right half of the thorax in nearly or quite the condition of a year earlier. There were marked dullness and bronchial breathing over the upper lobe, while below the third rib the note was nearly flat, resistance was extreme, pectoral fremitus was diminished, and breath sounds were feebly bronchial. The side was manifestly smaller than was the other. In addition to these findings, however, there were impaired resonance at the left apex with broncho-vesicular respiration and fine moist râles, the signs which are universally thought to indicate an early stage of pulmonary tuberculosis. The essayist has recently learned that the patient subsequently went to Asheville, N. C., and there died of consumption this last spring. The termination of the case seems to bear out his original diagnosis of its tubercular nature. That at the time of his first examination the lung was in a state of pneumonic consolidation, and not collapse, seemed to him certain from the physical findings. There was pleuritic exudate, but the insignificant degree of pressure, as shown by physical signs, and the results of two aspirations and the persistence of the physical signs afterwards, the evident cirrhosis of the lung a year later, all indicated, he believes, that the pleuritis had been followed by pneumonia of the interstitial type, or if of a broncho-pneumonic form, then, at all events, with subsequent fibrosis and not softening, as is usual, in tuberculous pneumonias.

Dr. Babcock detailed three additional cases resembling in many respects the first one narrated. In these four cases he was impressed by several quite peculiar circumstances: The patients did not seem very ill and judged by the mildness of the pyrexia and other symptoms their illness seemed to be of a low grade of activity. All but one appeared to have recovered and are now in good health. To judge from the extent and degree of dullness, one would have expected considerable effusion. Yet the insignificant degree of pressure effects and the result of tapping demonstrated that the exudate was poor in serum and rich in fibrin, and that the degree of dullness and the quality of the respiratory sounds at the apex could not be due to pressure or fluid in the lung, since the amount of fluid

was in reality small. 3. One has since died of pulmonary tuberculosis and in two of the others the personal and family history was that of tuberculosis. 4. Examination of the sputum, when any could be obtained, failed to reveal tubercle bacilli. He believes that in three instances, at least, there had existed a small tubercular focus at the apex, and that from this focus bacilli were carried by the lymph-stream, in a reverse direction, to the pleural cavity. They there set up a pleuritis which was chiefly fibrinous. From this pleuritic exudate, germs were carried to other parts of the lung and there excited a pneumonic inflammation which was interstitial and tended to fibrosis. In this way, the upper lobe as well as the pleura was involved in the process, and this combination accounted for the physical signs and subsequent findings after a lapse of many months.

DR. N. S. DAVIS, JR., emphasized what Dr. Wells had already said in regard to the prophylaxis of croupous pneumonia. The members of the profession have been very remiss in attempting to practice any measures that would be prophylactic in this disease, and particularly remiss in teaching the public that prophylaxis is possible. It is frequently said in the recent literature of the subject that the disease is becoming more and more prevalent and fatal. Certainly, statistics would seem to show that, and yet if we stop to think a moment these statistics are drawn almost exclusively from large cities in which the population is unusually dense, and has been increasing during the last ten or fifteen years and growing more and more dense during that time, so that we have conditions present in those centers from which we draw statistics which would naturally propagate the disease most rapidly and cause its spread most generally. It would be interesting if the statistics from large cities could be contrasted with equally correct statistics gathered from smaller cities and smaller places to ascertain whether the increase in prevalence and fatality of the disease is the same in the smaller communities as it is in the larger ones. He has an impression, but no facts sufficient to substantiate it, that it is the concentration of the people rather than the modes of life which renders them less resistant to disease which has caused an unusual spread of the malady and an unusual fatality. Destruction of the sputa of pneumonic patients should be done with as much thoroughness as it would be done in cases of tuberculosis, and it is infinitely easier to carry out because of the comparatively short duration of the malady.

DR. ARNOLD C. KLEIS stated that discussions with reference to pleuritic affections being tubercular have been going on for a long time. Osler, in 1893, examined the postmortem records of the Johns Hopkins Hospital, and found in 101 cases of acute pleurisy 32 cases that were tuberculous. The conclusion drawn by Osler at that time was that the proportion of tuberculous cases was not great. Not long ago Osler seems to have changed his opinion on that point, and believes that the proportion of tuberculous cases now is much larger. Dr. Kleis thought the modern view seems to be distinctly in favor of considering the majority of cases of acute pleurisy, with great thickening of the pleura, unattended with pneumonia induration, as being of tubercular origin.

DR. WILLIAM E. CASSELBERRY stated that it did not follow that a pleuritis occurring in a tuberculous patient is necessarily tubercular. At the same time, the two conditions are so closely conjoined, so far as prognosis and treatment are concerned, that we must recognize a tubercular pleuritis. He finds in looking over his records for the last ten or fifteen years that the majority of his cases of pleuritis, some of which were acute in character, are well and in good health to-day. One or two of them he recognized at the time as probably being tuberculous. He believes they have recovered from tubercular pleurisy. One of his cases was distinctly syphilitic; it is well recognized by authorities as being the result in some cases of secondary and tertiary syphilis, and such cases, under treatment, recovered.

DR. ARTHUR DEAN BEVAN said that post-operative pneumonia interested surgeons, and that some light had been thrown upon its etiology recently, since the introduction and more

extensive use of local anesthesia in operations. Surgeons only comparatively recently have recorded most of their post-operative pneumonia as being due to the irritation of the anesthetic, to the inspiration of food particles, or noxious material during anesthesia. Post-operative pneumonia frequently follows laparotomy, or more frequently operations upon the stomach, the bile tracts, and the structures in close contact with the diaphragm than upon other abdominal viscera. Since so much work is being done on the stomach, it has been found statistically and by individual experience that pneumonia is one of the most common causes of death after these operations. Many surgeons, in order to avoid this common cause of death, in these operations, have independently come to the same conclusion, that it would be well to do all the operations that can be done of this character under local instead of general anesthesia, with the idea that this would do away with the deaths from pneumonia following operations. After a considerable number of operations have been done under local anesthesia, however, it has been found in analyzing the statistics that even a greater proportion of cases die from operations of this character done under local than under general anesthesia.

DR. ALEXANDER HUGH FERGUSON favored lancing or puncturing the lung between the ribs when resolution should take place and failed to do so. If resolution of the affected lung could be hastened, it was worthy of trial. In the surgery of other organs this was being initiated during the last five or six years.

DR. E. H. OCHSNER said he had had the same experience as Dr. Bevan, although he confined his work entirely to general anesthetics at first, and found that lobar pneumonia was of common occurrence in cases which had undergone severe operations on the stomach, like resections of the pyloric end, gastro-enterostomies, etc. To overcome this difficulty he had found it advisable to have patients sit up soon after an operation, and it has been remarkable how much less frequent complications have been since. When he now performs a gastro-enterostomy the patient is allowed to sit up the next day in a semi-recumbent position, which is changed just as one would change the position of a patient with a fracture of the hip. In order to avoid this complication, and since he has adopted this method, the number of cases of pneumonia following major operations upon the stomach has been reduced very materially.

DR. BABCOCK, in closing, stated that with reference to the frequency and mortality of pneumonia within the last ten years, he felt sure that the statistics are not incorrect which show that this disease has been more than usually fatal in that period of time. Liebermeister, in Epstein's "Practice," says something on this point. He makes the statement that prior to two decades ago pronounced and typical cases of croupous pneumonia were much more prevalent than they are to-day; that the cases were more typical of genuine lobar pneumonia, and that within the last year or so, since the advent of the influenza bacillus, the pneumonias have changed a good deal in type, in that they have become atypical, and the increasing mortality of pneumonia within the last decade can perhaps be attributed to other things, as, for instance, mixed infection.

#### **Arthritis Deformans in a Child, with General Lymph-Gland Enlargement and Splenic Tumor.**

DR. A. F. LEMKE read a paper on this subject. In May, 1900, a boy, 11 years of age, entered Cook County Hospital with a history of an illness dating back to his 3d year, and a condition principally of the joints and lymph glands; that for a time, at least, forced the essayist to suspend judgment as to the diagnosis. The joint involvement alone seemed easily accounted for, but the very marked enlargement of the glands, and particularly those glands associated with the joints most advanced in the disease process, or most acutely involved, was not easily explained. The axillary glands were so enlarged as to be visible from a distance, and the epitrochlear glands were as large as a hazelnut. This picture of universally enlarged glands made one consider seriously the possibility of a tubercular infection, and with a view of definitely determining this a large gland was removed from the axilla, used to inoculate a guinea-pig, and examined bacteriologically and histologically,

as will be described later. The result of this inoculation was negative, and therefore the case was considered one of arthritis deformans, as it is occasionally seen in children, associated with lymph-gland enlargement and splenic tumor.

The general condition of the patient, after the ordinary tonic treatment, gradually improved, so that he was able to leave his bed and wheel himself about in a chair; but the condition of the joints, glands and spleen remained about the same, with the one exception that motion of the head was less painful. The blood state had also considerably improved. He was discharged Sept. 22, 1900, and not seen again until Nov. 1, 1901, when an examination revealed almost identically the same condition described above, except that the axillary lymph glands on the left side were slightly smaller. The course that the disease in this case has taken and the negative results of an attempt to prove the gland involvement tubercular warrant the essayist in grouping the case with nineteen or twenty others seen and described by George F. Still.

DR. FRANK X. WALLS said he had seen one typical case of arthritis deformans that occurred in a child 2 years of age, following closely an attack of measles. The smaller joints, as those of the hands and feet, were involved symmetrically. The case was under his observation for over a year, and during that time there did not seem to be any change in the course of the disease except that there were sometimes slight remissions and again a little improvement. The disease persisted from that time without any marked change. It did not respond to the antirheumatic, nor to tonic, treatment. There was general enlargement of the glands, but not to the extent mentioned in the case of Dr. Lemcke. He saw another case in which there were not so many of the joints involved. This case followed an attack of scarlet fever. The larger joints were involved, two elbows, and one shoulder joint. In another case the spine was involved following closely an attack of gonorrhea. The cases he had seen seemed to point to a group of complications following the different infectious diseases in children.

DR. ROBERT B. PREBLE stated that an interesting phase of this disease was its etiology. Without making any effort at classification, he believes that it will become necessary to subdivide the cases that are now designated by the name arthritis deformans. However, for the present he thought the term arthritis deformans was a useful one to maintain. It committed the physician to nothing. So far as the etiology of the disease is concerned, there are three conspicuous theories. One of the theories is that of infection, and while he is perfectly aware that numerous observers have found in the joint fluids bacteria of various sorts, he is not inclined to believe that the cases are due to infection. His objection to that theory is mainly this, that the joint involvements are symmetrical. This is perhaps truer of the adult cases than in those which are observed in children; nevertheless, it is one of the conspicuous clinical features. It was difficult, in his opinion, to see how infection could bring about a symmetrical distribution.

DR. E. H. OCHSNER reported a case that had been under his observation for at least four and a half years, the etiology of which he thought was plain. A young lady developed arthritis deformans slowly, beginning to be ill in 1893. In 1897 she came under his care, with almost every joint in the body involved. She was so crippled that she could not walk, nor feed herself. She was absolutely helpless. Her weight when she came under his care was 87 pounds. After she had been under his care for some time, although it was difficult to elicit any information from members of the family or from the patient regarding the various functions of the body, he found that she was suffering badly from hemorrhoids, and that sometimes her bowels would not move for a week or ten days. He operated for the relief of the hemorrhoids, and was surprised at the condition in which he found the lower bowel. He had never seen such an accumulation of foul fecal matter. Although strong cathartics were given, the fecal matter resembled putty, and the state of decomposition was bad. The sphincters were thoroughly stretched, the hemorrhoids were

removed, and the woman, so far as the acute symptoms are concerned, has recovered. He has found it necessary to break up several of the joints, and to put the legs in a straight position. Patient is now able to walk and has gained 53 pounds in weight. In this case he thought the cause of the arthritis deformans was a constant auto-intoxication, and if the nature of the disease had been determined two or three years earlier than it was the woman might have been saved from the calamity in which she has fallen now.

Dr. J. RAWSON PENNINGTON said that arthritis deformans is sometimes associated with rectal ulceration; Wallis, Cave, and others have reported such cases. He detailed two cases occurring in women.

Dr. EDWARD F. WELLS pointed out that the essayist had presented the report of a case of a specific disease *an generis*; that Dr. Still had likewise reported similar cases, but he did not think the paper should be loaded down by discussions regarding ordinary cases of arthritis deformans.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, X.

(Continued from page 198.)

#### Chemical Incompatibilities.

Chemical incompatibility may be apparent in three ways:

1. By precipitation or the formation of insoluble compounds.
2. By the evolution of gas.
3. In some instance by changes in the color of the mixture.

The largest class is included in the formation of insoluble compounds by precipitation. This precipitation takes place when two salts, combined, form an insoluble salt by the interchange of radicals. The most important incompatibilities are included in the following table as arranged alphabetically by M. L. Neff, for the convenience of the practitioner:

1. Acids or acid salts are incompatible with: alkalies and alkaline salts; alcohols (tinctures) and glycerin; hydrates and carbonates; glucosids; bases; relatively weak or volatile salts.

2. Alkalies are incompatible with: alkaloids and their salts; chloral; acids and their salts; relatively weak salts (halogens); metallic salts; calcium and magnesium salts.

3. Alkaloids and their salts with: alkalies; alkaline salts; halogen salts; tannic acid; phosphoric acid; boric acid and sodium borate; hydriodic acid; carbonic acid and the carbonates.

4. Arsenic is incompatible with: tannic acid; salts of metals, especially lead and silver; lime; magnesia.

5. Aqueous solutions are incompatible with: chloroform; metallic salts; essential and fixed oils; alcoholic tinctures; fluid extracts; resinous tinctures.

6. Hydrargyri chloridum mite (calomel) with: antipyrin; alkalies (lime water, etc.); potassium iodid; salts of iron and lead.

7. Carbonic acid and carbonates are incompatible with: iron salts; metallic salts (especially iron); salts of magnesium and calcium; acetic acid (syrupus scillæ).

8. Aqua calcis is incompatible with: salts of mercury (sometimes intentional); carbonates of alkalies; morphin and quinin salts.

9. Mucilages are incompatible with: alcohol and nitrous ether; iron; aqua plumbi; mineral acids.

10. Nitrous ether (sweet spirits of niter) is incompatible with: tincture guaiac; mucilages; antipyrin; Ferri sulphas; most of the carbonates.

11. Oxidizing substances, including the permanganates, chlorates, nitrates, etc., are incompatible with: charcoal; ammonium chlorid; tannic acid; sulphur; glycerin.

12. Phosphoric acid and the phosphates are incompatible with: alkaloids; metallic salts; salts of magnesium and calcium.

13. Tannic acid is incompatible with: alkaloids; metallic salts (especially iron and lead); arsenic; digitalis; albumins and gelatin.

14. Gentian preparations will produce a change of color in the mixture when combined with: iron salts; infusion of prunus virginiana; infusio cinchona comp.; silver nitrate; lead salts.

The following prescriptions will illustrate some of the chemical incompatibilities of the foregoing list, as given by Seville and Thornton:

R. Hydrargyri chloridi corros. gr. i 065  
Potassii iodidi 3iv 15  
Aqua, q. s. ad. 3iii 90

M. Sig.: One teaspoonful after each meal in water.

In this prescription potassium iodid precipitates red mercuric iodid, which is redissolved in the excess of potassium iodid. This prescription is sometimes intentionally ordered.

R. Hydrargyri chloridi corros. gr. i 065  
Potassii iodidi 3ii 7 50  
Tinct. cinchona comp. 3iii 90

M. Sig.: One teaspoonful three times a day.

In the above the potassium-mercuric iodid precipitates the alkaloids in the cinchona, demonstrating that alkaloids should never be combined with soluble iodids or corrosive sublimate, which are powerful precipitants of the alkaloids.

R. Hydrarg. chlorid. gr. iii 20  
Tinct. cinchona co. 3vii 210  
Spts. ammon. arom. 3i 30

M. Sig.: One teaspoonful as directed.

This is both ambiguous and incompatible. If the first ingredient means corrosive sublimate, ammoniated mercury will be formed; if calomel, black oxid of mercury will be formed.

R. Pot. bromidi 3iii 11 25  
Chloralis hydratis 3ii 7 50  
Spts. ammon. arom. 3ss 15  
Syr. zingiberis 3i 30  
Aqua 3iss 45

M. Sig.: Take one teaspoonful and repeat in two hours.

The chloral is decomposed by the alkaline spirits of ammonia, chloroform being formed.

R. Acidi nitromuriatici dil.  
Spts. ammonia arom. 3i 3 75

M. Sig.: Two drops in water every four hours.

One of the above ingredients neutralizes the other.

R. Argenti nitratis gr. x 65  
Cocaine hydrochlor gr. xii 75  
Aqua 3i 30

Silver chlorid is precipitated if dispensed as written. This may be prevented by using cocaine nitrate in place of the hydrochlorate.

R. Syr. scillæ 3i 30  
Syr. senegæ 3ss 15  
Pot. bicarb. gr. xx 1 30  
Tinct. opii 3ii 7 50  
Syrupi q. s. ad. 3iv 120

M. Sig.: One teaspoonful four times a day in water.

The syrupus scillæ contains acetic acid, which neutralizes the ammonia in the syrupus senegæ and causes effervescence.

R. Ammon. carb. gr. xx 1 30  
Spts. etheris nitrosi 3i 30  
Tinct. ferri chloridi 3ii 7 50  
Liq. ammon. acetatis, q. s. ad. 3iv 120

M. Sig.: One teaspoonful every three or four hours.

The ammonium carbonate is incompatible with the ferric chlorid and spirits of nitrous ether, unless care is observed in the compounding.

R. Quininæ bisulph. 3ss 1 88  
Liq. ferri et ammon. acet. 3ii 60

M. Sig.: One or two teaspoonfuls three times a day.

In this combination the insoluble quinin acetate is precipitated.

(To be continued.)

**Lactic Acid in Alopecia.**

Balzer, in *British Medical Journal*, recommends the following lotion in the treatment of alopecia: After cutting the hair close to the scalp and cleansing with soap and water the following should be applied:

|                                     |         |     |
|-------------------------------------|---------|-----|
| R. Hydrargyri chloridi corros ..... | gr. iii | 20  |
| Acidi acetici .....                 | gr. xv  | 1   |
| Alcoholis .....                     | ℥iv     | 120 |
| Etheris .....                       |         |     |
| Sol. lavendulæ (alcoholic) āā ..... | ℥i      | 60  |

M. Sig.: Apply locally once a day.

After drying, the head is rubbed with lactic acid, about 30 per cent.

**Improved Method of Introducing the Stomach Tube.**

It is exceedingly difficult to introduce the stomach tube for the first time; and the effort is not infrequently abandoned. Crenshaw, in *Med. Rec.*, suggests a new method of overcoming the nausea and gagging, by freezing two or three inches of the end of the tube in ethyl chlorid. When it is introduced it causes anesthesia of the mucous membrane with which it comes in contact. It can, he claims, in this way, be introduced very easily for the first time. When it reaches the stomach the temperature has been sufficiently raised to cause no harm.

**Treatment of Passive Congestion of the Liver Due to an Incompetent Heart.**

Dr. Bommier, as stated in *N. Y. Med. Jour.*, recommends, in these passive congestions, cardiac tonics such as digitalis, caffèin, spartein and strophanthus. The following combination is also employed by him in such conditions:

|                                |         |   |    |
|--------------------------------|---------|---|----|
| R. Ext. ergotæ (aqueous) ..... | ℥i      | 3 | 75 |
| Pulv. scillæ .....             | gr. xlv | 3 |    |
| Hydrarg. chloridi mitis .....  | ℥ss     | 1 | 88 |
| Pulv. digitalis .....          | gr. xv  | 1 |    |

M. Ft. pilulæ No. xl. Sig.: One pill three times a day.

**Treatment of Scarlatinal Nephritis with Hot Water Irrigations.**

Kerly, as noted in *Ther. Gazette*, recommends irrigation of the colon with hot water as the best means of restoring the functions of the kidney in scarlatinal nephritis. It should be employed whenever the quantity of urine is diminished or when convulsions occur. In a child aged 3 years, 500 to 750 c.c. of water at a temperature of 43 C. should be introduced by means of a rectal tube passed into the rectum for a distance of 2.5 centimeters. If the water is returned at once it must be repeated and irrigation continued every six or eight hours. After three or four administrations the kidneys commence to act as a rule and abundant diuresis takes place.

**Medicolegal.**

**Promise of Third Party to Pay Doctor's Bill.**—The recent Nebraska case of *Swigart vs. Gentert* was brought to recover from the party sued for services rendered as physician and surgeon to his daughter, who was a married woman, and was at the time living with her husband. The testimony of the party sued was: "That plaintiff [the doctor] called me out. He set in buggy, and I walked up to him. Then he told me, 'Your daughter is pretty sick.' I was a little scared, you know, so he says, 'I guess I get her through all right.' After that he asked me, 'Who is going to pay that?' I told him, 'I help you see you get it,' but I never promised anybody." The jury apparently accepted this version of the transaction, and the Supreme Court of Nebraska holds that the promise stated was one clearly within the statute of frauds, that is to say, one to answer for the debt of another, and one required to be in writing to bind the party sued. His promise was twofold—First, that he would help the doctor to collect the bill; and, second, that he would see that the doctor received his pay. The first part of the promise could not be enforced because of its indefiniteness; and the second part was, by its very terms, a promise to answer for the default of the parties who would be primarily liable for the services to be rendered. The fact that the doctor would not render the services upon the responsibility

of the daughter and her husband, without the additional promise of the party sued to see that the doctor received his pay, the court holds, was not of itself sufficient to take the promise out of the statute of frauds, in other words, to relieve it of the necessity, under the statute, of being in writing to be binding. Furthermore, the court holds that testimony that the doctor never presented a bill for the services to the party sued was competent, and properly admitted, it being proper to be taken into consideration, with the other evidence in the case, in determining to whom credit was extended. Nor does it consider erroneous an instruction in which the jury was told that if the party sued advanced to the doctor \$20 for and on behalf of his son-in-law, after the services were rendered, such act would not be a confession nor an admission of liability on the part of the party sued for the remainder of the bill.

**Examining Physician's Statement—Employing Physician.**—The Supreme Court of Michigan says, in the case of *Rhode vs. the Metropolitan Life Insurance Company*, that it does not appear that the question was ever before presented to it, in just the form that it was here, as to the admissibility in evidence, as against the insurance company, of the statement of the examining physician, made at the time of the examination of the applicant for insurance. But it has no doubt, on principle, that such testimony is competent evidence against the assured. The physician, it then proceeds to say, is a representative of the insurance company. He is employed for the very purpose of determining the physical condition of the applicant. His examination is supposed to be made with the utmost care, and with due regard to the interests of his employer. And the court declares that it can conceive of no reason why his statements, made at the time, should not be received as competent evidence, that is, as against the company. It does not mean to intimate, however, that such testimony is conclusive, but that it is receivable, as bearing upon the question of the condition of health of the applicant at the time the examination was made, it thinks is clear. Another point in this case was with reference to the effect against him of the statement of the assured, contained in his application, that he had not been under the care of a physician within two years. In certain previous cases the court has held that merely calling upon a physician for some temporary indisposition, which does not tend to weaken or undermine the condition of the assured, would be no breach of the warranty. But, in each of those cases, it now points out, the party suing offered affirmative testimony to show that the treatment of the physician was for some temporary indisposition. Neither of the cases held that it is not sufficient, prima facie, to show a breach of a warranty such as that involved in this case, to prove that the assured had, in fact, been attended by a physician. Indeed, to so hold, the court insists, would be doing violence to the very terms of the stipulation. So, when, in this case, the company was prepared to show that the assured had, within two years prior to the making of his application, been attended by one or more physicians, this, the court holds, was prima facie a breach of his contract, and the burden would be upon the party suing to recover the insurance to show that the attendance was not for any ailment which tended to weaken or undermine his health seriously.

**Furnishing Physician—Power of Director—Not Expert.**—The Supreme Court of Vermont says, in the personal injury case of *Sias vs. the Consolidated Lighting Company*, that it thinks the mere fact that an employer furnishes a physician or nurse for one who meets with a disabling accident in his services ought not to be received as evidence tending to establish his liability. It must be the impulse of every humane employer to provide this assistance for a disabled workman without means, and the rule of evidence ought to be such as to permit his doing it without danger to himself. Such an act should be treated as a humane recognition of an existing necessity, and not as an admission of the justice of a claim not then asserted. Then, a physician called as a witness was permitted to testify that when he was with the party suing about a week after his injury, another physician, who was a director in the corporation sued, called, and, on leaving, told him to go on

with the case, in consequence of which he sent this bill to the company, the director having also stated at the time that he called to see the young man in the interest of the company in place of the manager. But the Supreme Court holds that the admission of this testimony was erroneous for the reason above stated, and also because it did not appear that the action of the director was authorized by the company. The mere fact that he was a director, the court holds, did not authorize him to act for the company in this manner. A director of a corporation can bind the company by his separate action only so far as he may be authorized to do so. In undertaking to act singly for the company he must be looked upon as an ordinary agent, and the rules of evidence applicable in cases of agency must be applied. If there be matters which it is *prima facie* the duty of a director to attend to, this cannot be held to be one of them, for it was not within the scope of ordinary corporate duty. If it was a matter in which the manager could bind the corporation, the declaration of the director could not be taken as evidence that he was authorized to act in place of the manager. Again, the court holds that it was error to admit the evidence of the witness who took the x-ray photographs of the injured joint, explaining that the reason why there were no light lines running across at the foot of the perpendicular bones of the leg was because there was a fracture close to the ankle joint, which afterwards filled up with cartilage. The witness subsequently testified that in the experience he had had in photographing ankle joints in their natural condition the light lines appeared between the bones, and upon further inquiry that he had taken some 1600 pictures of joints in different parts of the body, and that he considered himself qualified to say whether the white line would appear in a joint in normal condition. This, however, the court holds, did not make him an expert as to the character of the injury and the subsequent process to which this difference in the photograph was due.

## AMERICAN.

1. **Procidentia Uteri.**—Noble's method in the average case is to curette, which is only of special value in hypertrophy of the uterus with hyperplasia of the endometrium; he follows this by amputation of the cervix, which lessens the weight of the uterus and promotes involution. He makes a resection of the anterior vaginal wall, which serves to remove the redundant or overstretched walls; he next performs perineorrhaphy, and finally suspensio uteri. In the less severe cases a smaller series of operations may be performed. He gives the details of each of the operations and tabulates his experiences.

2. **Gonorrheal Vulvovaginitis in Children.**—The conclusions of Peterson's article are: 1. Vulvovaginitis in the young girl may be divided into simple and gonorrheal. 2. Simple catarrhal vaginitis is due, in a large majority of cases, to lack of cleanliness, and subsides when the proper treatment is instituted. 3. Gonorrheal vulvovaginitis in young children is more common than is generally supposed. While more frequently met with amid unhygienic surroundings in large cities, it is by no means a rarity in the less thickly settled districts. 4. Gonorrheal disease is more frequent below the age of 6; it is more common in girls than in boys. 5. Specific vulvovaginitis in the large majority of cases arises from actual contact of the patient with some infected person. A study of the reported epidemics, however, shows that the disease may be spread by other means, such as a common bath, towels, bed-linen, etc. 6. The ordinary staining methods will prove satisfactory in making a differential diagnosis between specific and other forms of vulvovaginitis. 7. The parts affected in their order of frequency are the labia, urethra, vagina and cervix; the vagina is more frequently affected in the child than in the adult, owing to the character of its epithelium. 8. The tubes, ovaries, and peritoneum may be involved in the pathologic process. It is not improbable that certain diseases of adult life may be ascribed to gonorrheal infection in infancy. 9. Purulent ophthalmia and rheumatism are quite frequent complications. The strictest prophylaxis should be observed in order to avoid the former. 10. The treatment of specific vulvovaginitis must be energetic to be of any avail. Under certain conditions the vaginal orifice should be widely dilated and the vaginal pus cavity properly drained.

4. **Cesarean Section in Placenta Previa.**—Ehrenfest argues against the propriety of Cesarean section in placenta previa, reviewing the arguments and reporting cases. His conclusions are as follows: 1. The results of Cesarean section at large are worse than is usually stated. 2. In contradistinction, the results obtained by the usual treatment of placenta previa are by far better than is generally believed. 3. There is every reason to expect that the results of Cesarean section performed in cases of placenta previa will be much worse than those of the classic operation. 4. If Cesarean section as a means of treating placenta previa is contemplated, Porro's radical operation, with extirpation of the uterus, according to the indications for this operation, may have to be performed in the majority of cases. 5. The treatment of placenta previa by means of Cesarean section does not seem to hold out promise of considerably augmenting the number of children saved. 6.

A careful study of the published statistics shows that the most promising treatment of placenta previa is the following: From a careful study of the statistics the author finds that the best treatment of placenta previa is in cases of deep seated previa, where late appearing hemorrhages can often be stopped by accelerating the progress of the labor, by artificial rupture of the membrane. If the bleeding continues, however, while the head is low down, a tight tamponade of the vagina is indicated, fixing the bleeding edge of the placenta between the fetus and the tampon. In this the tampon does not push out the placenta from the uterus, as occurs when the presenting parts are not fixed in the pelvis. After awhile the tamponade should be removed in order not to retard the progress of the child, and if the head is deep enough and the canal fully dilated the forceps can be applied. In cases of abnormal position or perforation of the cord, bipolar version, according to Braxton Hicks, should be performed as soon as two fingers can be passed into the cervical canal. This is possible usually in the case of placenta marginalis, and the turned fetus can be pulled down until the knee can be seen. In this case the thigh and breech act as a tamponade from above. Further expulsion should be left to the natural powers of the uterus and forced extraction after the version has been performed should not be undertaken. A very deliberate and careful extraction may be attempted in some cases, but only if there is a chance to save the life of the fetus. In case of central previa, the first hemorrhage often sets in during pregnancy or in the early stages. Sometimes the break can be checked by keeping the patient confined to bed and applying douches of cold water, but if these fail, abortion should be induced immediately, opening the canal with the Hegar's dilator until a colpeurynter can be introduced, following with a 2 per cent. solution of lysol, and expulsion by uterine contraction awaited. Light, careful traction at the free end of the colpeurynter is permissible, which is best done by means of a 2-lb. weight. Immediately after the bag is passed through the cervix, bipolar version is performed. In order to rupture the membranes an attempt should be made to reach the end of the placenta, but a thorough search for it is dangerous. If the membranes can be reached they are ruptured and the foot pulled through the opening. If they can not be reached easily the fingers penetrate the placental tissue and the foot is brought down through this hole. If at the time when the hemorrhage begins the cervix allows of the introduction of two fingers a dilatation is not necessary, and bipolar version is immediately performed. Further treatment is the same as described for marginal previa. In central cases even a careful manual extraction should not be attempted, as in these cases the lower segment of the uterus here is very friable and the danger of rupture imminent. If version has been made and the cervix not been injured, the hemorrhage is always checked immediately. None of these procedures are difficult or require special measures.

5. **Ventrofixation and Its Influence on Labor.**—The points made by Jacobson are that serious difficulties in labor have occurred only when the methods of operating have produced widespread and dense attachment of the fundus to the abdominal wall. He thinks shortening of the round ligaments as in the Alexander operation, and especially the Goldspohn modification, are better for subsequent pregnancies than are other methods. Apparently from the statistics the operations of suspension and ventrofixation reduce fertility. This can not be positively stated. They have no special tendency to induce abortion. As regards practical obstetric conclusions, plastics failing, it would seem that suspensio uteri, possibly after the Kelly method or one of the other methods such as Alexander's, is infinitely preferable to permanent ventrofixation, except, of course, in elderly women or those whose ovaries have been removed. From an obstetric standpoint, ventrofixation may be considered as occupying an intermediate plane between vaginal fixation and ventral suspension. As a rule pregnancy and labor are uncomplicated, between 85 and 90 per cent. have been absolutely normal; in 2 per cent. delivery has been impossible by the natural method. In the remaining cases the difficulties have been overcome by ordinary obstetric resources. We have,

notwithstanding, some good obstetric reasons for distrusting the operation of ventrosuspension in child-bearing women.

**9. Chronic Myocarditis.**—From a review of the subject, including its various types and a report of several cases, Musser concludes as follows: "We may say, then, that myocarditis may exist, 1, without definite physical signs—a rare occurrence I believe; 2, with signs of moderate cardiac hypertrophy, marked reduplication being the only physical sign and of significance only when coupled with signs of endarteritis; 3, with physical signs of dilatation; 4, with physical signs of fatty degeneration; 5, with the physical signs mentioned, which in the aggregate are of great significance."

**10. Digitalis.**—Jacobi calls attention to the fact that he has long urged the use of digitalis in small doses for various cardiac conditions and tuberculous disease, giving from 4 to 6 grains daily or its equivalent, given for weeks or months or even years without any hesitation. He finds no cumulative action in the use of the drug in this form. The patients do not become accustomed to its effect so as to reduce its efficiency. The indications for the use of digitalis, according to this method, are insufficiency of the heart muscle and incompetency of the mitral valve. Chronic myocarditis is no contra-indication and aortic insufficiency when incipient or moderate and not causing inconvenience is also perfectly compatible with this medication. In advanced cases where compensation is much disturbed and considerable peripheral venous obstruction exists even digitalis will not suffice to restore the equilibrium between the action of the heart and the distended capillary circulation. He also mentions as of value small doses of digitalis in cirrhosis.

**11. Heart Strain.**—Carter's article reviews the subject of heart strain, giving the symptoms, treatment, etc. It can not be abstracted in detail.

**13. Bacteriologic Diagnosis of Typhoid Fever.**—Higley notices the different tests of typhoid fever, the Widal reaction and His' isolation method. The question is: Which is the best aid in the diagnosis of typhoid? In clinical practice patients with typhoid present themselves at various periods of the disease. They may be classed, however, in two divisions: 1. Patients in the second, third and later weeks of the disease, in whom the characteristic symptoms have been developed and where something else than clinical symptoms must be called in for the diagnosis. 2. Patients in the first week of the disease where characteristic symptoms are not yet developed and where we have to make an early and sure diagnosis. In the first class of cases, except from the beginning of the fourth week on he prefers the isolation method. From the fourth week on he prefers the Widal reaction. The His method is preferred in the earlier period because it is the best, surest and easier method. In late cases isolation tests are useless, and the most favorable method is the Widal reaction and the leucocyte count. If we get positive results the better the diagnosis; if not, we have to wait. The bacteriologic examination of the urine he considers of little value from the diagnostic standpoint, excepting in rare cases which are not seen until the convalescence is nearly established. The isolation of bacteria from the blood has difficulties, requiring at least 5 c.c. and the discomfort of the patient in obtaining this is a serious obstacle in private practice. He thinks it should be restricted to cases where other methods of bacteriologic diagnosis have been tried without avail.

**14. Traumatic Intracranial Lesions.**—Phelps advocates antiseptic exploratory craniotomy where there is any reason to suspect depressed fracture. For intracranial hemorrhages he considers the justifiable use of operation is limited, and invasion of the cranial cavity without definite indications unjustified. The justifiable conditions of head injuries he says may be summarized as properly general in depressed cranial fractures, frequent in comparatively uncomplicated epidural hemorrhages, and exceptional in subdural lesions, whether of the brain or of the pia-arachnoid membrane. The question of operation will often be raised and definite decision entail great responsibility, but the accidents of too early or unwarranted

invasion may outnumber those where ultra-conservatism has led to fatal neglect.

**15. Tuberculosis.**—Minor concludes his article, giving explicit directions as to sputum disposition and the keeping of the case record by the patient himself; he believes that this is beneficial. In all but severe cases a trained nurse can be dispensed with. All the paraphernalia he recommends are a reclining chair capable of being put into a horizontal position, good rugs, woolen underwear, and sputum cup. A tin bathtub and bath thermometer are all that is necessary for the hydrotherapeutic treatment. The more intelligent the patient the less frequently will the physician need to be consulted; generally from one to two visits a week will be sufficient. The amount of rest is a matter for judgment as is also that of exercise; the latter should begin moderately. The patient should not be left to his own judgment in the matter until he is able to walk for an hour or more. Minor believes in pulmonary gymnastics as being of value. Other matters mentioned are amusements, worry, which should be avoided, of course, hardening of the body by hydrotherapy, etc., and symptomatic medical treatment. He concludes with a day's routine for a consumptive case and a bibliography.

**16. Cystocoele.**—Brettauer advocates Freud's method of treating defects in the posterior wall of the bladder by plastic use of the uterus, and proceeds in the following way: After the usual preparatory measures, an incision is made through the anterior vaginal wall, from the urethra near its orifice to the cervix; two flaps are bluntly dissected, the bladder loosened and pushed upward as far as possible; the vesico-uterine fold of the peritoneum is then opened and the fundus of the uterus dislocated through it. In two cases in which the uterus was retroflexed, this was done by means of a sound. The posterior surface of the uterus is now fastened with three sutures of chromic gut to the flaps of the anterior wall of the vagina, about one-half inch from their edges. In the first case the flaps were not resected, but sewn together with a running suture, and a colpo-perineorrhaphy added in the usual way; in the second and third cases, the flaps were united after resecting a strip about one-quarter of an inch in width. The vagina was then packed with gauze and the patient put to bed. He has operated thus in three cases, which he reports, the results being good in all. The operation demands less time and is accompanied by less bleeding than in any other method so far employed by him. Of course, its usefulness is limited and only patients near or past the menopause can be subjected to it, but in old women where prolonged operation is contra-indicated, the method deserves a thorough trial.

**24. Inoperable Tumors.**—George reports cases of treatment of sarcoma and granuloma treated with pyoktanin and Coley's serum. The former seemed to reduce the size of the tumor, but there was excessive stimulation of growth of tumor cells in the neighborhood and while there was temporary relief the patients ultimately became worse and died. In one of the serum cases, a granuloma, the results were not especially beneficial. The tumors continued to increase in size in the sarcoma case; in the granuloma there was gradual disappearance of the tumor by local necrosis and sloughing, but the tumor began to grow again and was extirpated surgically. The sarcoma case terminated fatally. Two other cases have been treated in the Michigan University Hospital with Coley's mixture, without benefit, one of carcinoma and the other of lymphosarcoma. Therefore, the author concludes that his experience has been unfavorable to its use.

**25. Diphtheria Antitoxin.**—The duration of immunity produced by immunizing doses with diphtheria antitoxin according to various authorities is discussed by Jump, who reports five cases, from which, with the experience of others, he feels warranted in deducing the following conclusions: 1. That as diphtheria antitoxin is practically harmless, all exposed persons should receive an immunizing dose in proportion to age. 2. That 250 units should be given to children under two years and 500 to all others. 3. That the immunity will last for at least three weeks, provided a reliable antitoxin is used. 4. That

all exposed persons should be removed from infected surroundings, either by thorough disinfection of their own quarters or by removal to other places. If this be impossible, the immunizing doses should be repeated every third week.

**26. Follicular Tonsillitis.** Dulles' treatment is to avoid strong antiseptics and treat his cases with small doses of calomel and soda and saturated solutions of boric acid as a gargle or rather as a wash. In very little children he orders instead the administration of lime water every hour throughout the day. If this is administered a little while before the calomel is given he holds that it does not form black wash in the stomach, and he has seen no interference with the action of calomel by this treatment. In older persons where there is a good deal of pain he has found it of advantage to give salophen or salol and phenacetin in sufficient doses. He finds that it relieves the pain and he believes it also has a systemic action. He believes in giving rest to the digestive tract in these cases and finds it advantageous to have no food given until the patient, if old enough to speak, asks for it. In some cases that he saw, with much pain and congestion, he found the application of dilute solutions of adrenalin chlorid of seemingly great advantage.

**27. Ear in Influenza.** The importance of aural complications in influenza is dwelt upon by Smith, who thinks the first manifestations should receive prompt and energetic care. Hot antiseptic solutions are most useful in many acute cases of otitis and hot medicated solutions are not specially the better for the drugs contained. The ear should be frequently examined and prompt incision of the tympanum, before waiting until it is too much distended, should be performed. Many cases will then make a good recovery with antiseptic irrigations followed by introducing a strip of iodoform gauze well into the deep canal, to provide for good drainage, removing it every day or two. We must, however, endeavor to rid the ear of bacteria by keeping down the inflammatory heat and keeping the surface dry. After the secretions have been removed by irrigation, irrigation or a cotton carrier, the surface can be gently dried with cotton and hot air, and dusted with some impalpable powder, such as aristol or nosophen, care being taken to only dust the surface, leaving no excess there to be impacted or interfere with drainage.

**31. Phthisiophobia.**—Knopf deprecates the irrational fear of tuberculous contagion and criticizes the head of the Marine-Hospital Service for giving out the opinion that it is dangerously contagious with the result of stopping incoming immigrants who may be suffering from it. He also notices the growth of this idea among the laity and the recent action of the village health board of Liberty, N. Y., and other places. He calls attention to the fact that it is conclusively proven that since the establishment of sanatoria for consumptives, the disease among the villagers of Goerbersdorf and Falkenstein has been actually decreased by one-third of what it was before the establishment of the institutions. The article is a plea for sanatoria for the care of the needy consumptives.

**32. Narcolepsy.**—After reporting a case of diurnal morbid somnolence preceded by free perspiration, lack of refreshment from the physiologic sleep, weak, slightly hypertrophied heart, dilated stomach and hypochlorhydria, with high urinary density and acidity, excess of chlorids, sulphates, urates, etc., in the urine, diminished blood alkalinity and small reduction of hemoglobin and a low degree of relative urinary toxicity, Stern discusses the subject and seems to hold that the primary cause is a toxæmia of some form. He suggests that the excess of chlorid excretion exhausting the supply and causing temporary diminution of chlorid in the blood, which plays an important part in osmotic tension of the body fluids, may be probably the cause of the condition.

**33. The Tonsils.**—Bosworth argues that the tonsils are not a normal physiologic growth, but a distinct menace to health. He reports his method of operation under chloroform with a cold wire snare in preference to the tonsillotome. This diminishes the danger of hemorrhage, which is an important consideration, especially in adults.

**34. Appendicitis and Typhoid.**—The difficulties of diagnosis between appendicitis and typhoid perforation are pointed out by Richardson, who reports a case illustrating them. The main points, he says, to be emphasized in determining between typhoid and appendicitis are that when any of the local signs, pain, tenderness, rigidity and fever are absent, especially tenderness and rigidity, it strongly suggests typhoid. The case must be studied with special care lest typhoid be overlooked; so too, when the constitutional symptoms outweigh the local. Without pain at some time in the course of the disease, there can be no acute surgical lesion of the abdomen; temperature with pain, but without rigidity or tenderness, means typhoid fever or simple continued fever; very high temperature should excite suspicion if pain and tenderness are present but not marked, for acute appendicitis has usually a moderate temperature; a soft abdomen with a high temperature is a suspicious combination, even if there is pain and tenderness; when typhoid is suspected, the pain and tenderness must be distinctly localized in the appendix, and confirmed by rigidity, resistance or tumor, before operation for appendicitis is justifiable. When there is doubt as to typhoid, the operation should be postponed if constitutional signs are severe, and local ones hard of detection. When the abdominal symptoms—pain, tenderness, rigidity, with or without distension—call loudly for operation, the abdomen must be opened, in spite of the possibilities of typhoid; but cases suggesting typhoid as strongly as appendicitis, should until the diagnosis is perfectly clear, be carefully observed.

**35. Fractures in Children.**—The chances of fractures occurring in children and being overlooked are pointed out by Cotton and Vose. There may be only slight symptoms of pain and there is a kind of subperiosteal fracture which is practically common in children, most of the cases reported being of this type. The patients were subjected to skiagraphic examination, the treatment being simple fixation for two or four weeks with perfect results. We are inclined to underestimate the tolerance of children to fractures. In adults there are not infrequent exceptions to the rule that fractures entail immediate and notable pain and disability; but in children the exceptions are so numerous as to require a modification of the rule. In small children if there is a history of a fall or other trauma, especially where the arm or shoulder girdle may be involved, the only safe way is to assume fracture until every inch of the bone has been gone over carefully.

**36. X-Ray Burns.**—Rollins claims to have proven that x-ray burns can be produced by x-light in electricity and by electricity when no x-light is present. He gives an account of his experiments on guinea-pigs and points out that not only burns can be produced on such animals, through a single thickness of aluminum, but they can be killed by light after it has passed through two aluminum screens. X-light, he claims, after excluding the participation of all other agents in the results, is a force of great power, and thinks there is a chance for useful original work in this field.

**40. Consumption.**—Monroe gives a number of facts bearing on the hereditary transmission of tuberculosis, showing where the descendants of one parent in a family had all died from the disease while the other parent and his and her children by another partner have been perfectly free from it. He does not find any case of infection in his experience, but refers to a great many other cases where there has been a family inheritance.

**41. Hepatic Cirrhosis.**—Witherspoon's article is largely a general discussion of the subject, and he calls attention to the importance, in operative treatment, of early union of the liver with the abdominal wall so as to insure a general circulation at least in the peripheral hepatic cells and protect the patient from the ill effects of intestinal intoxication. It is also well to perform an omentopexy at the same time, and relieve the portal circulation before the ascites is well established.

**51. Jaundice.**—Mayo concludes from his study of the subject that jaundice is not to be expected in uncomplicated gallstone disease. When due to stone obstructing the common duct there is a history of previous attacks of colic. The symptoms vary

considerably. There can usually be obtained an early history of some little fever, sometimes chilly sensations or sweats. The gall-bladder often can not be palpated. In malignant disease the loss of flesh before the jaundice, the age of the patient, the non-improvement of the jaundice, with a distended and perhaps nodular gall-bladder or adjacent tumor, completes the clinical picture. When due to chronic pancreatitis it will probably be confused with malignant disease; hence, the possibly existing cause would suggest examination as to history, age of the patient, and duration of the symptoms. The various forms of cirrhosis accompanied by jaundice are to be distinguished by examination of the liver and occasionally the size of the spleen. Every practitioner is familiar with the catarrhal jaundice that is most common in young adults and is due to an extension of a mild infection from the gastro-intestinal tract; the age of the patient, slow pulse, lack of general symptoms and the short duration make the diagnosis easy.

**62. Stitch Abscesses.**—Maylard has experimented with patients in which he had previously rubbed in oleate of mercury to determine whether this bactericidal agent could hinder or prevent the production of "stitch abscess," and the actual presence of mercury in tissues under the skin was tested chemically and the fragments of the skin were subject to bacteriologic examination. Chemical examination failed to afford any positive information. Either the mercury was in too small quantity to be detected, or its absorption and transit through the lymphatics too rapid to be caught for analysis. The bacteriologic examination proved a material diminution in the number of micro-organisms present. The ointment could not reach every possible location; therefore, some escaped. The clinical records seemed to afford incontestable proof of the value of the method. He advises the preparation of the skin for operation with lanoline oleate of mercury ointment, by first cleansing the skin by turpentine water, alcohol and ether, if necessary; then rubbing in lanoline oleate of mercury and leaving on a piece of lint besmeared with same until the second incision is performed twelve hours later. Every case should be treated for at least twenty-four hours before operation, preferably forty-eight hours, with at least two separate periods of "rubbing in" for about ten minutes on each occasion. The lint is removed on the operating table and the superfluous ointment rubbed off with a piece of sterilized gauze.

**66. Intestinal Approximation.**—Frank believes in the Murphy button and he finds that von Bergmann, Gussenbauer and Wölfler, who condemned it four years ago, have within the last year come out strongly in its favor for end-to-end union. Czerny has been using it since 1896. He thinks that for simplicity, time-saving, uniform coaptation of peritoneal surfaces, arrest of hemorrhage, prevention of contracted cicatrix, juxtaposition of histological structures, avoidance of infection, less disturbance of the peristaltic wave, avoidance of pocketing and shelving, reduction of mortality, and in the minimum mortality it surpasses all other methods.

**67. Carcinoma of the Cecum.**—Before describing their cases Cumston and Vanderveer discuss the subject, diagnosis and technique of the operation according to various authors.

**76. Uncinariasis.**—A description of the parasite, symptoms, etc., and a history of the disease in the United States are given by Claytor, who reports a case. He thinks there is an increasing danger of the greater prevalence of the disease from its importation by immigrants from localities where it is prevalent and by those returning from our newly acquired territories.

**80. Thoracic Aneurysm.**—Three cases are reported by Arnold. In the first the aneurysm was not the immediate cause of death, but the author thinks it undoubtedly had an important contributing influence through the attacks of prolonged extreme dyspnea which diminished the resistance of the patient to pneumonic infection which carried him off. In the second case the aneurysm caused the death by inducing aortic regurgitation, dilatation of the left ventricle, mitral regurgitation, general passive congestion and death from asystole, accompanied by edema of the lungs; the responsibility of the aneurysm

was indirect. In the third case the pressure of the distended sac interfered with the circulation, causing death, while in the fourth it prevented entirely the exit of air from the lungs, and the patient died of suffocation. With the descent of the diaphragm on inspiration the heart and anterior part of the arch were drawn downward, allowing the air to enter the lungs, but not allowing it to escape. Still another case is reported in which death was caused by starvation from pressure of the aneurysm on the esophagus.

**81. Tuberculosis in Heart Disease.**—The conditions noticed by Anders are: 1. Endocarditis due to tubercle bacilli, which is illustrated by a single case in his experience, and is so rare as to be almost non-existent. 2. Cases of recent endocarditis and chronic endocarditis that are secondary to tuberculosis or merely intercurrent, and are caused by various non-tuberculous infections and other agencies. Such cases do occur and include many of the cases ascribed to tuberculous infection. 3. Forms of chronic valvulitis that are primary and precede the tuberculous infection of the lung, and are ascribable to rheumatism and other recognized causes. This is the most important group and is naturally non-tuberculous in its etiology. It is believed that the effect is different according as it is on the right or left side of the heart. Valvular lesions of the left heart apparently protect against tuberculosis while stenosis of the pulmonary artery predisposes. As appears from a careful review of the literature aortic valve disease seems to be rarely associated with phthisis. When the disease, however, attacks the individual the lung disorder aggravates the cardiac affection.

**84. Echinococcus Disease.**—Lyon summarizes the reported cases of echinococcus disease in North America and discusses the relation of age, sex, occupation, the geographical distribution, diagnosis, etc. He finds that a great majority occur in foreigners, a very large percentage being Germans, and most of the cases are reported from New York and Manitoba. The most frequent anatomic location of the parasite is naturally in the liver. It can not be authoritatively said whether the disease is increasing or not, but it seems to be in domestic animals. He calls attention to the importance of looking out for future possibilities, especially regarding infection of man from dogs, and we should protect our dogs from the infection of diseased cattle, sheep and swine. We can exterminate the disease by enforcing proper sanitary regulations at the slaughter houses. Without such precautions we may expect the condition of Germany and Australia in respect to the number of lives sacrificed to this disorder which has as yet no serious foothold among us.

**85. Herpes Zoster.**—From a discussion of the conditions and theories Van Harlingen comes to the following conclusions: "1. Under the designation zoster or herpes zoster, is to be understood a specific infectious and possibly contagious exanthem, characterized in its invasion by lassitude, general malaise, chills, increased temperature, and more or less digestive disturbance. Following this, in most cases, neuralgic pains develop along certain nerve-paths or metameric areas, together with the development of enlarged lymphatic glands. After a period of several days, more or less, during which the symptoms mentioned, or some of them, have manifested themselves, the characteristic exanthem shows itself, and runs through a fixed cycle of development, acme and decrudescence. The general symptoms, particularly the neuralgic pains, may continue during this period, or, in many cases, may diminish, usually disappearing with the eruption. In other instances, and particularly in older persons, the neuralgia may form a prolonged succedaneum to the regular course of the disease. In a certain number of cases, probably however rare, various visceral complications may accompany the affection. Such are paralysis of sensory or motor nerves, inflammations of the pleura, peritoneum, articulations, or viscera. 2. The infection attacks chiefly the posterior (sensory) ganglia of the cord and the Gasserian ganglion. From hence inflammation and degeneration may extend along the nerve trunks and fibers. No other lesions have as yet been discovered post-mortem, although it is probable that further observation will result in tracing the disease in the various membranes and

viscera when its presence has been clinically noted. The numerous examinations of the skin lesions and such blood examinations as have been made have not as yet thrown any light upon the nature of the disease. 3. Zosteroid eruptions are not infrequently observed in cases of poisoning from coal gas, after the ingestion of arsenic, following injuries of the nerves, as a result of moral shock, as grief, or in hysteria, and probably under other conditions. These, however, are to be distinguished from the true herpes zoster as defined above."

**91. Graduated Responsibility.**—Richardson's article is a plea for the partial responsibility of the insane and he shows how many cases of insanity are yet more or less responsible and holds a plea of irresponsibility should not be held as an extenuating circumstance as regards the duration of the confinement. The man who escapes on this plea should not be allowed at large; more care should be exercised in preventing a person of limited mental capacity from returning to the environment that produced the original act, and the release in all cases should not be unconditional. A single offense of such individuals should be taken more frequently to indicate a propensity from which society should be protected. He asks why can not the legislature authorize the judge to instruct the jury to consider the degree of moral and mental incapacity of the individual as well as the character of the act with which he is charged, and if the jury finds the acts and probable motive to indicate such moral deficiency or propensity or weakness as would render it unsafe for the persons again to gain their liberty, let it be empowered to recommend an indefinite confinement, and why should not the judge be given some discretion as to the kind of institution to which such persons should be sent?

**93. Examination of the Stomach Contents in the Insane.**—The importance of gastric disturbances of insanity is insisted upon by Allen, who gives the results of examinations for gastric lesions in the Michigan Asylum. A number of cases are reported of stomach examinations and treatment based upon these produced good results.

**94. The Wills of Lunatics.**—Buckler's article is a medico-legal review of the law as regards the testamentary capacity of the insane. He summarizes the legal standing in this regard as follows: A person of unsound mind may make a will as valid as that of any other person, unless in the opinion of a jury his power of rational action is destroyed by general mental disease, or by some partial mental disorder affecting the performance of that particular act. The question of undue influence is also a matter for the jury or judge to pass upon. Each case here depends upon its special circumstances.

**95. Psychic Treatment.**—Runge gives an interesting report of the results of moral treatment, and the methods employed in the St. Louis Insane Asylum. He goes over the questions of the influence of patients upon each other of religious exercises, occupation, amusements, etc. In only one instance does he mention absolute defeat of all measures of psychic treatment for the benefit of the case.

**96. The Insane Criminal.**—An analysis of 400 cases admitted to the Massachusetts Asylum for Insane Criminals is given by Metzger with comparison with some of the New York statistics. He finds a bad family history in a very large percentage, 59.4 per cent, have a bad heredity as regards insanity, epilepsy and alcohol. In those cases admitted within the last two years where the history has been looked into somewhat more carefully the percentage of bad heredity rises to over 70 per cent., and still higher figures are afforded by the Matteawan State Hospital of New York. Crimes committed by the insane vary as widely as those of the ordinary criminal; in a very large percentage the criminal career was entered upon at an early age, in nearly all before the age of 25. The majority of insane criminals are multiple offenders. Every type of insanity is represented; the percentage of cases of dementia precox is especially large, and many of them have also a strong alcoholic factor or element of inebriety. Many of the cases classed as alcoholic are very unstable mentally and might have become insane even if they had not been intemperate. Metzger thinks that too much stress can not be laid upon the number of insane men who have been condemned to prison with mental

defects unnoticed or disregarded, and gives an enumeration of such patients that have later come into his hands. The offense committed by the individual is by no means the criterion by which to judge of his danger to society. Of 400 men, 216 were apparently irresponsible at the time they were tried, but only 40 of these were recognized as such. He thinks that a plan of medical supervision of all arrested individuals would be a good thing, and it could be more easily carried out in the larger cities where the necessity of such foresight is most required.

**101, 102. Neuron Retraction.**—The paper by Weil and Frank gives the history of theories of neuron contractility, description of the methods employed by them, and of the results. They limited their attention to changes in the dendritic processes of the pyramidal cells of the cerebral cortex and corroborate the statement of Cajal that normal and toxic matter can not be differentiated by the number of varicosities or gemmules. Moreover, different pieces of the same material, whether toxic or normal, vary greatly in the proportion of varicosities and of gemmules. Admitting these objections, they think the theory of retraction is deprived of all anatomical evidence. They also believe that the proportion of varicosities is largely dependent upon the method employed, and they must be regarded as artefacts. There is, therefore, no morphologic basis for the theory of retraction. There are many physiologists who hold to the belief that this theory offers the only possible explanation of certain groups of nervous and psychical phenomena. They do not deny that there may be retraction, or an allied process, but assert that the Golgi method in the present state of its development is incapable of demonstrating this fact.

The same subject is viewed from a psychic standpoint by White, who claims that while histology has failed to establish the fact it is strongly corroborated by the facts of psychopathology. He has been able in a number of cases to apply this theory after making the diagnosis and formulate a system of treatment which gave good results. He holds that it may be in some respects analogous to the atomic theory, only demonstrable by phenomena and not by the microscope.

**103. Identification of the Insane.**—The application of the Bertillon system of identification to the insane, or a modification of it suited to conditions, is advocated by Winter and Steinbach, who mention instances where serious mistakes have been made in identification of the insane who come to asylums and are unable to give an account of themselves and with very imperfect histories. They give tables and figures illustrating the cards and instruments employed.

**106. The Cephalic Index.**—The general deductions from statistics that have been made seem to indicate that a comparative dolichocephaly means inferiority, while comparative brachycephaly is the hallmark of mental superiority. Winter's observations, however, do not quite bear this out in his study of British crania, and seem to support the theory that an unusual increase in the relative width of the head, among the British at least, is indicative of psychophysiologic variability, often accompanied by mental and moral instability.

**107. The Sacral Cord.**—Onuf's studies of the sacral region of the spinal cord are elaborate, and want of space forbids their detailed reproduction here.

**111. Tumors of the Corpus Callosum.**—Putnam and Williams report three cases of callosal tumors and analyze the symptoms. They give also an appendix additional with thirty-eight tabulated cases from the literature, which are also analyzed. One striking fact is the predominance of mental symptoms in cases of tumor localized in this region and the frequency of excitability over depression. In many cases, however, the condition may be latent over a considerable period. The anatomic and physiologic considerations are discussed and the authors come to the conclusion that the brain can be considered simply as an instrument, a series of sensori-motor mechanisms, a multitude of threads stretching from periphery to periphery, devoid of the power of storage of memories and without any exclusive intellectual center, to more readily explain the symptoms of tumor of the corpus callosum. The sole function of the brain consists in bringing about actual motion or nascent motion. It exists for nothing else; and mental life consists in clothing these actions, which seem to

be concerned only with the needs of the present and the future, with the colors and forms drawn from the life of the past. Into each act of the present the whole of the actor's past enters in some measure.

**119. Diagnosis of Ocular Paralysis.**—Duane gives a table of diplopia in paralysis and sums up his conclusions in regard to this subject in the following: 1. In the case of paralysis of an elevator or depressor it is immaterial for the diagnosis whether a lateral diplopia is present or not and whether, if present, it is homonymous or crossed. The diagnosis in these cases is to be made from the character of the vertical diplopia (or vertical deviation behind the screen) and from the way in which this diplopia increases in looking up or down, and especially in looking toward the four corners of the field of fixation. The character of the diplopia in looking straight up or straight down affords no certain criterion for the diagnosis, but we must ascertain how the diplopia changes when the eyes are directed respectively up and to the right, up and to the left, down and to the right, and down and to the left. The diagnosis then is readily made from the table given. 2. From the same table the diagnosis can readily be made in cases of combined paralysis. 3. When diplopia is absent, the diagnosis can still be made, in marked cases at least, by the screen test, performed with the eyes directed respectively up and to the right, up and to the left, down and to the right, and down and to the left. The deviation behind the screen in each instance will correspond in character and amount to the diplopia that would be ordinarily produced by the paralysis, and the diagnosis here, too, can be made from the table just as if diplopia was present.

**133. Hospitals for the Insane.**—Hill gives the history of the Board of Control Management of the Iowa State Hospitals. It appears that the civil service rules are not very elaborate, but a non-partisan board assures against political influence in the management and great benefit has been derived from this fact. The superintendent has absolute control of the appointment and discharge of subordinates and nothing is stated as regards the examinations for minor offices.

**141. Tuberculin.**—Cornick has had good satisfaction in the use of tuberculin for diagnostic purposes. After first securing a temperature record of the patient, taken every two hours from 8 a. m. to 8 p. m., for two or three successive days, he gives from 1 to 5 milligrams of tuberculin subcutaneously at 8 p. m., doubling the dose again in forty-eight hours, and again doubling at the end of every forty-eight-hour period until the temperature rises two degrees, as shown in excess of the same hour the previous day, in which case the diagnosis is positive, or until the limit of 20 or 30 milligrams has been reached for the final dose without such reaction which excludes tuberculosis. He uses the standardized tuberculin prepared by the Bacterio-Therapeutic Laboratory, of Asheville, N. C., and a 1 per cent. dilution for the beginning dose with a 10 per cent. dilution, if necessary, at the last. Sterilized water containing .5 to 1 per cent. carbolic acid is the best diluent, and the locality used is the loose cellular tissue over the back in the interscapular space. He has employed tuberculin also therapeutically with advantage, as he claims, but considers that this use must be limited to very early stages of the disease where it has a great curative value.

**142. Yellow Fever.**—Oliver argues from records of past epidemics that the mosquito theory of transmission of yellow fever is false.

**147. Typhoid Perforation.**—The occurrence of typhoid and its frequency is discussed by Taylor, who holds that possibly one-third of the deaths from typhoid are due to this complication. The surgical treatment, of course, is the only method that offers hope. The difficulties of diagnosis are noted and he says that his experience prompts him to attach most importance to the following: 1. Pain. 2. Muscular rigidity. 3. Inhibited peristalsis. We need more proficiency in the diagnosis than in the operative technique. We should bear in mind that perforation is usually located in the last eighteen inches of the small intestine, and should not be too much perturbed in regard to shock. When this is absent or is not dangerously profound, immediate intervention is indicated.

**150. Typhoid Fever.**—When called to a case of typhoid Hubbard usually commences by giving the patient a capsule of calomel  $\frac{1}{2}$  gr., guaiacal carbonate 2 grs., podophyllin  $\frac{1}{40}$  gr., every two hours for twenty-four to forty-eight hours, depending upon the condition of the bowels. He continues this until he has secured four or five intestinal evacuations for two successive days, and then discontinues calomel and uses  $\frac{1}{2}$  gr. of menthol added to the guaiacal and podophyllin. If after discontinuing the calomel there is a tendency to inaction of the bowels, he gives a small dose of salts or Hunyadi water in the morning, and always tries to get two or more evacuations daily. If after three or four days of treatment the temperature remains high or rises, he again uses calomel every twenty-four hours or less, which invariably reduces the temperature and results in general improvement. He continues the guaiacal and menthol throughout the disease. He thinks the efficiency of this method is demonstrated by clinical results.

#### FOREIGN.

**1. Epilepsy.**—Broadbent commences by saying that epilepsy is a disease of which we know extremely little definitely, and with certainty nothing at all. We are fairly agreed as to the cases to be called epilepsy and have a considerable knowledge of the etiology, but its pathology is largely conjectural and its treatment empirical. After first reviewing the well-known symptoms he refers to some points of particular importance. One is, fits rarely come on during work or excitement. We need not forbid epileptics to take exercise, to ride or even to cycle in moderation. In the causation of the disease the most important element is undoubtedly heredity or the inherited tendency to predisposition, though it may exist without any such, other than can be excited by peripheral irritation. Sufficient importance has not been given to the sensory nerves in this disease. We can inhibit the attack sometimes through these, and it seems reasonable that they may excite it. As regards the pathology he holds to the Jacksonian theory of nerve discharge and nerve instability, using the usual terms in this explanation. As regards the prognosis, he thinks if epilepsy does not occur in a low type of nervous organization, and the attacks do not begin in infancy or puberty, but only after some serious exciting cause and late in adolescence or adult life, there is a possibility that it may be held in abeyance. The state of the circulation is a matter of importance. Prolonged observation has convinced him that the tension of the pulse is unduly low in epilepsy. This he considers is characteristic, while a high tension pulse for the age of the patient is ground for hopefulness. He mentions a case which seemed to bear out this view. As regards treatment, open-air life, exercise of almost every kind, care as to diet, but without any special prohibitions, avoidance of overfeeding and having the evening meal always light are advised. Stimulants, however, must be forbidden. He would not prevent an epileptic boy or girl going to school unless the fits are very frequent, excepting for the fear of disturbance the fit might make with other children. We should study the hereditary tendency, avoid exciting causes, look after dietetic derangements and especially the menstrual period if irregular or accompanied with pain. He believes that bromids are given too much in a routine way and the question is whether relief of the symptoms may not be too dearly purchased by these depressing drugs. He thinks that if Julius Caesar and Napoleon, who are said to have been epileptics, had been treated with bromids they would not have amounted to so much in the world. The rules he lays down for himself are to give the bromids simply to diminish the frequency of the fits, while other means should be employed to reduce the instability of the system. In cases where the fits are not frequent he does not give the bromids regularly, but with premonitory symptoms these should be taken up. When they are frequent they should be given in such amounts as may be necessary and at such hours as may be suggested by the time in which the fits are liable to occur. If the fits are nocturnal we may possibly be able to do something by regulating the cardiovascular instability. Thorough examination of all the bodily organs and functions should be made and he believes in

keeping down the pulse tension in exceptional cases where high pressure exists. For lowered vitality give phosphorus, hypophosphites, arsenic with strychnia and sometimes iron, and he thinks arsenic itself has a beneficial effect on the disease. The condition will bear a great deal more study than it has as yet received.

**2. Cancer of the Breast.** Banks' article is largely a historical résumé and argument claiming the credit for himself and others which has been of late years given to Halsted for his thorough operation.

**3. Oophorectomy in Cancer.** Batlin in his article does not support the idea of any special positive relation of the existence of the ovaries to cancer of the breast and the benefit of oophorectomy. He believes in local operation. In many cases it may be successful, and if the disease still continues and kills the patient it may do so in some distant organ with much less pain and suffering. Moreover, if it recurs *in situ* in the patient in the form of nodules she generally suffers far less than if no operation had been performed. We are asked to replace the operation by the removal of the ovaries and the administration of thyroid and he says we can only reply that so far as known there is no single case of cure by means of oophorectomy. Even if after operation and oophorectomy the disease returns it is in no way improved by the latter operation. He says that if we are to come to a definite opinion as to whether oophorectomy can cure any woman of cancer it must be by applying the practice in say twenty or twenty-five cases where it exists to a very mild extent without any obvious extension to the lymph glands. If a surgeon can find that number of patients willing to take the risk he does not blame him for performing oophorectomy, but he would not have the courage or faith himself to do so.

**5. Inheritance.**—Mercier's article is a scathing criticism of the recent views of Archdall Reid and his criticism of the medical theories of the transmissibility of acquired characters.

**6. Phantom Tumors.**—The paper by Bennett is a clinical lecture on phantom tumors in which he describes cases of these due to local irritation, either superficial or internal, to occupation and to imitation. Phantom tumor is not a disease in itself, but simply a sign of some concurrent disease or eccentricity. When caused by local irritation the source of the latter may be immediately in relation with the phantom, or it may be more or less distinct or remote from it. As a rule the nature of the cause can not be determined until the tumor itself has been allowed to subside under anesthesia. He suggests in doubtful tumors keeping the possibility of phantom tumors in mind. Sometimes examination in sleep will settle the matter, but some persist during sleep. The important detail in anesthesia for diagnosis of these cases is to place the hand gently upon the tumor from the time of commencement of giving the anesthesia. It will be found that during the early stage of the anesthesia it increases a little in size and hardness, but with the oncoming of complete anesthesia little vibrations or quivering motion will be felt, and then it will perceptibly melt away gradually under the hand. Such tumors never disappear suddenly, and this is a matter of importance. If the tumor suddenly slips away the evidence of positive tumor is sure. It has slipped back into the abdomen, say for example, instead of being possibly a mere muscular contraction of the rectus. Another point he calls attention to, is putting the warm hand flat over the part. The pain, muscular rigidity, and other difficulties caused by the indiscriminate manipulation by cold hands and finger tips account for many errors in diagnosis. As regards treatment there is not much to be said. In irritation cases the cause should be removed if it has been discovered. In occupation phantoms, rest from the occupation may give relief; but change of occupation is necessary for a cure. The imitation phantom is generally of small consequence; the patient should be kept from association with the person imitated. Galvanism vigorously applied may afford relief.

**8. Internal Derangement of the Knee Joint.**—The article by Barker discusses the conditions following splitting and dislocation of the semilunar cartilage in its various forms. In

operating on these cases the incision he uses is one commencing over the inner border of the ligamentum patellæ about one half inch above the articular border of the tibia and carried with a curve downward and outward to the anterior ridge of the internal lateral ligament. The lowermost edge of the flap so formed should be about one half an inch below the anterior border of the tibia. The cut should be firmly made and divide the periosteum. The flap should now be raised with the periosteum until the edge of the cartilage appears under the attachment of the meniscus, which, if still attached, will raise with the flap until its under surface is seen. If partially torn anteriorly it can be stitched to the periosteum with a few silk threads. The periosteum is now laid back in its place and secured there by silk stitches, the meniscus becoming firmly attached to it. The rest of the wound is closed without drainage. If complete peripheral separation has taken place recently and the curled up meniscus can be easily reduced in flexion to its old position it can also be stitched as above, but when this separation is old and the cartilage is shrunken up around the crucials it is better, by snipping its attached ends with scissors, to remove it completely. The same is true in cases of "central splitting" where the partial rent is behind the internal lateral ligament. Here it is better to complete the rent and take away the whole meniscus. Great care should be taken to avoid touching the parts with the fingers. Nothing but carefully sterilized medical instruments and sterilized gauze should be used. Antiseptics should be avoided; they cause irritation and the wound should not be kept open a moment longer than necessary. Ice-bags over the dressings for the first week or so are agreeable and probably keep down the effusion.

**9. Scurvy.**—The three recent theories of scurvy—that of Wright that it is due to acid intoxication, that of Liston that it may be caused by ankylostoma, and that of Jackson and Harley that it is a condition of ptomain poisoning—were tested clinically by Lamb. He finds that in his cases there was nothing to support the view that any of these was correct. He comes to the conclusion, therefore, that scorbutic symptoms, though associated in some cases, like those of Wright's, with a condition of acid intoxication, may develop entirely independent of this condition. There appears to be no one etiologic factor and pathologic condition underlying the symptoms clinically known as scurvy.

**14. Glycosuria and Insanity.**—Dawson reports seven cases of glycosuria associated with insanity in which the symptoms were local discomfort in varying degree and the blood pressure was high. Glycosuria is not necessarily a bad symptom, as five of his seven cases made good recoveries and another seems to be on the road to recovery, while the remaining one is for other reasons a hopeless case.

Bulletin de l'Académie de Médecine (Paris), December 24.

**Sero-Vaccination of Hog Cholera.**—One of the prizes of the Académie was awarded to Professor Leclainche of Toulouse for his successful sero vaccination of hog cholera. He reports that 30,272 animals have been treated on these principles, and the results have been as successful as during the first trials. Even in an advanced stage of the disease—which runs a very brief course—the animals can be saved by the prepared serum. Its efficacy is comparable to that of antidiphtheritic serum, but even surpasses it. Phagocytosis is always active in this disease, even when it terminates fatally, but when aided by the prepared serum it is stimulated to such an extent that the animal recovers. Leclainche supplements this effective but transient serum protection by inoculation of the virus, which confers durable immunity.

**Resolution on the Prophylaxis of Malaria.**—The Académie unanimously voted in favor of a resolution urging the government to special legislation to enable the inhabitants of Corsica, Algeria and other colonies of France to obtain quinin everywhere, of a good quality and at a low price, as has been accomplished in Italy by the law passed Dec. 23, 1900. This established a maximum rate of 40 centimes for two grams of quinin hydrochlorate and of 32 centimes for the sulphate. Merchants distant more than 500 meters from a pharmacy are

allowed to sell the quinin, which is prepared in the government factories.

**Transmissibility of Human Tuberculosis to Animals.** S. ARLOING.—Every one of the 23 animals in Arloing's tests showed tubercular lesions and more or less severe symptoms of tuberculosis, after they had been inoculated with human bacilli from three different sources. They included 4 calves, 6 sheep, 4 goats and 3 asses, all species which Koch declared to be non-tuberculizable by human bacilli. Arloing compares his tests with those of Koch and states that he administered larger doses, using 2 to 4 c.c. of a 1 to 25 emulsion, while Koch used a 1 to 500 to 5000. Arloing concludes that as the virulence of the tubercle bacillus is variable, and as it adapts itself to certain organisms, it is not surprising that the bacillus derived from man may display less activity on certain animals than the bacillus of bovine tuberculosis. It is possible, he asserts, to find and cultivate human bacilli capable of transmitting tuberculosis to cattle, sheep and goats. He, therefore, persists in assuming the unity of human and bovine tuberculosis from the Koch bacillus. He also insists that impartial study of Koch's report shows that the experiences on which he bases his assertions did not justify him in such absolute distinctions. Three of the tests which he states were negative, should really be classed as positive, as also his four "dubious" cases.

Bulletin de la Soc. d'Electrotherapie (Paris), November.

**Electric Treatment of Sprains.** PLANET and CHARRIER.—The pain is the obstacle to the mobilization of the joint in case of sprain. Faradization for five to ten minutes a day completely banished the pain in a number of cases of both recent and chronic sprains described by Planet. As soon as the pain was arrested the patients could mobilize the joint without trouble, and thus prevent or cure the functional impotence of the injured limb. The electricity was applied once or twice a day until the cure was complete.

Bulletin de la Soc. des Hop. de Paris, December 26.

**Mitral Endocarditis with Vegetations, Ulcerative Aortitis and Incipient Embolic Aneurysm of the Abdominal Aorta.** HUCHARD.—A young man, healthy except for an apparently brief attack of syphilis five years previously, exhibited symptoms of pseudo-intermittent febrile, infectious endocarditis, which terminated fatally in fifteen months with the complications mentioned above. Huchard concludes from the study of this and similar cases that infectious diseases are liable to produce circumscribed arteritis sooner or later, frequently due to an embolic process, and terminating in an aneurysm of rapid development. In other cases the aneurysm may develop rapidly on a chronic aortitis. The infectious disease may produce an aneurysmal tumor even after several years. The circumscribed ulcerative arteritis preceding the aneurysm may be produced by the embolic process or by the colonization of various micro-organisms in the previously altered coats of the artery. Le Gendre has observed a case of infectious endocarditis in which embolic accidents occurred several times, some of them affecting the nerve centers and causing right hemiplegia with aphasia, left hemiplegia and brachial monoplegia, all of which passed away in turn. During the intervals, the patient, a child with mitral and aortic valvular defect, apparently recuperated his health until he finally succumbed to infarct of the kidneys. In another case an embolic aneurysm of the humeral artery developed acutely during an infectious endocarditis and colonies of streptococci were found in the walls of the artery as well as in the infarcts in the spleen and kidneys, evidently derived from the vegetations on the mitral valve.

Bulletin Medical de Quebec, December.

**Latent Endometritis in Pregnancy.** W. ALBERT has recently announced that germs from the vagina may infect the uterus at any age, but especially after menstruation has commenced. Every vagina contains germs, but Doederlein's bacillus is the only one to be found in normal conditions. The infection of the vagina, like that of the cervix and body of the uterus, after an acute, frequently slight and brief stage, may

become latent, and conception is possible in this latent stage of the affection. Many premature deliveries, septic abortions and cases of so-called post-abortion endometritis, many of the discomforts of pregnancy and the majority of puerperal accidents, may be attributed to a latent microbial endometritis, anterior to the pregnancy. His statements are based on more than 10,000 maternity or gynecologic cases. The *Bulletin* editorially confirms his statements and adds that the same cause is probably responsible for many pathologic alterations in the placenta, abnormal adhesions, etc., uncontrollable vomiting, eclampsia, nephritis and other pathologic processes. Prophylaxis should therefore aim to render the vagina aseptic, which would materially reduce the number of puerperal and post-puerperal affections. "At present our prophylactic measures against puerperal fever are instituted too late."

Presse Medicale (Paris), December 25.

**Splenic-Hepatic Asystolia.** P. OULMONT.—Hepatic asystolia is the term applied to cases of cardiac insufficiency characterized by hypertrophy of the liver. Oulmont has recently observed two cases of well compensated cardiac insufficiency characterized by hypertrophy of both liver and spleen. There were no venous anomalies and no history of preceding infections which might have injured the spleen, but both patients exhibited evidences of severe anemia, to which they finally succumbed. This anemia was accompanied by an increase in the numbers of hematoblasts, while the proportion of leucocytes was nearly normal. One patient was a man of 24 and the other a woman of 28. The cachexia was rapidly progressive after the congestive hypertrophy of the liver and spleen had developed.

**Clasp for Suture of the Bones.** A. JACOBEL.—The clasp is shaped like a double-pointed tack, only the space between the points is longer in proportion. The points are grooved in eight concentric circles. The edge of the spaces between the grooves flares slightly away from the point. This enables the clasp to take very firm hold of the bone and not slip out of place. The grooves are made on the principle of carpenters' nails so that the clasp will not crack the bone, when hammered into the holes made for them. One or two of these clasps will hold even a fractured clavicle solidly in normal position.

December 28.

**Intermittency of Argyll-Robertson's Sign in Tabes.** C. MANTOUX.—In a case personally observed and in three others Mantoux has collected, the pupil signs were intermittent during the course of tabes. The intermissions may be brief—a single day—or may persist for months. The appearance and disappearance of the signs seemed to coincide with gastric crises in the cases studied.

Progres Medical (Paris), December 21.

**Uremides.** P. RAYMOND.—Uremides are an eruption coinciding with other uremic manifestations, gastric, intestinal, pulmonary or cerebral. They are usually generalized and without any special arrangement, but they may become localized on the limbs, near the hips or shoulders, or in the back or over the sternum. Exacerbations are noticed with the variations in the renal lesions and fluctuations in the auto-intoxication. This eruption is essentially erythematous, but it may be vesicular, bullous or even purpuric, according to the layer of the derma involved. The lesions are essentially those of edema, with intense dilatation of the vessels and minute hemorrhages. They are not limited to the skin alone but are found also in the muscles beneath. Probably all the vessels participate in the dilatation. The uremide occurs when the kidneys are becoming less permeable, sometimes even in apparently mild cases of Bright's disease. As it indicates a more intense toxemia, it renders the prognosis grave, suggesting the approach of death. Only one of the six cases which Raymond has had occasion to observe, terminated in recovery. The others were all rapidly fatal. The uremide is probably due to the action on the nerves of the products of auto-intoxication, inducing vasodilatation and the consecutive cutaneous affection. It is probably more common than generally recognized, although

it by no means follows that every cutaneous manifestation in a uremic subject is necessarily an uremide.

Centralblatt f. Chirurgie (Leipzig), December 28.

**Per Oral Intubation.** F. KUHN.—The tube extends from the throat through the mouth to the outer air, instead of being made for the throat alone. It is of metal, flexible, with a curved guide inside. A cross piece on the outer end holds it in place in the corner of the mouth. A solid nut is fastened on the tube at the point where it passes between the teeth, so that it is impossible to close the jaws or bite the tube. The advantages of thus being able to ensure uninterrupted breathing during narcosis, a strumectomy, etc., render this peroral intubation a very valuable measure under many circumstances. It obviates the necessity of a gag and of pulling out the tongue. A very wide tube should be selected for a narcosis. The assistant can keep it clear of secretions with a small spiral brush. The most important indications for this peroral intubation are symptoms of compression, hitherto compelling tracheotomy. The danger of infection from a tracheal wound is avoided and the tube can be left in place for hours at a time. The second indication is to prevent aspiration of secretions and blood in operations on the upper air passages. The pendent position for the head becomes unnecessary with this intubation as it prevents aspiration and acts like a tampon for the lower portion of the throat. Even if nose, throat and tongue are packed so that breathing is impossible, except through the tube, it continues undisturbed. In case of asphyxia, air can be blown into the lungs through the tube by a rubber bulb. Kuhn has long advocated these flexible metal tubes—Metallschlauchsonden—for clinical diagnosis, especially for the alimentary canal.

Centralblatt f. Gyn. (Leipzig), December 6.

**Early Sign of Commencing Pregnancy and of Death of Fetus.** O. SCHAEFFEL.—An important sign of the changes in the circulation which accompany a commencing pregnancy, is a reddish stripe on a dull livid background, which runs across or slanting in the region of the urethra or the exterior of the tuberculum vaginæ. This stripe is evidently due to vasomotor influences directly dependent on the vitality of the fetus, as Schaeffer found that its disappearance coincided with the death of the fetus. Another sign of pregnancy to which he calls attention is the progressively increasing resisting power of the blood corpuscles in blood drawn directly from the portio of the vagina. A drop, representing about 1 c.mm., is mixed with 11 c.mm. of some fluid isotonic for healthy erythrocytes. In a fluid of this nature the vigorous corpuscles stain and shrivel while the weaker swell and grow pale and granulated. In a mixture of iodine, potassium iodide and water, for example, in the proportion of 1, 2 and 300, the strong corpuscles turn brown, the less resistant pale yellow, and the very weak remain glassy. Under ordinary conditions in healthy individuals with healthy genitalia, the dark-stained, vigorous corpuscles are in the proportion of 2.5 to 5 to one of the pale corpuscles. These proportions become progressively higher during a pregnancy. In a number of cases he found the proportions between 4.1 and 4.8 to one in the second month; between 6.2 and 7.5 to one in the third month; between 4.8 and 12 to one in the fourth to sixth month and between 4 and 24.2 to one in the seventh month. A sudden drop from a high to a low proportion was always followed by labor in two or three days. The drop indicates a decline in the arterial blood supply and extensive admixture of venous blood. The menstrual periods are marked during the pregnancy by a similar phenomenon on a small scale.

**Dysmenorrhea.** MENGE.—The menstrual blood in the uterus probably acts like a foreign body, Menge thinks, and it induces contractions of the organ and consequently labor pains. These contractions and pains in normal conditions are so slight as to pass practically unnoticed. They amount to dysmenorrhea only when some mechanical hindrance interferes with the flow or when it causes irritation of local pathologic conditions, or in case the nervous system is abnormally sensitive. Each of the three varieties, the mechanical, the inflammatory and the nervous, requires different treatment.

Dermatologisches Centralblatt (Berlin), November and December.

**Balsam and Salicylate Treatment of Gonorrhea.** S. BEHRMANN.—When balsam treatment is commenced early in acute gonorrhea the discharge soon loses its purulent character and the conditions generally improve. During this stage carbonated waters should be avoided. After the gonorrhea has lasted about four weeks and has been modified by the santal oil or other balsam administered, Behrmann believes that a point is reached when only a slight impulse is required to start nature on the road to complete recovery and prevent the transition into the chronic stage. This impulse he thinks can be found in the use of sodium salicylate. The salicylate is eliminated by the urine and mucous membranes, and its action is much more powerful in the presence of carbonic acid, consequently, wherever there is inflammation and swelling. It stimulates the tissues from within, and the complete restitution of Morgagni's crypts and Littre's glands is possible under its influence. The dose should be a tablespoonful every two or three hours of a 2.5 per cent. solution of sodium salicylate, until 15 gm. of the salicylate have been taken. It is well to keep up as much as 3 a day for some time after this. It should be supplemented by a carbonated water. The mild alkali in the water prevents the precipitation of the salicylic acid by the hydrochloric acid in the stomach and hence prevents gastric troubles and allows the salicylate to be long continued. It also increases the diuresis and thus brings the medicating substance into more frequent contact with the mucosa of the urethra. Binz has established that the action of salicylic acid is enhanced by the presence of carbonic acid. The latter has also a tendency to prevent shriveling. It promotes the retrogression of the lesions and thus favors restitution.

Dermatologisches Zeitschrift (Berlin), December.

**Retarded Healing After Radical Operation of the Middle Ear, by Chronic Urticaria.** WARNECKE.—A man of 40 was operated on for the relief of otitis of the middle ear which had recurred a number of times since childhood. The wound was healing normally when urticaria developed on the granulating surface and persisted for three months, thus postponing the healing of the large defect left after the operation. No medicines had any effect on the process.

Deutsche Med. Wochenschrift (Berlin and Leipzig), December 26.

**Plasma-Destroying Toxins in the Organism.** E. GRAWITZ.—The vicinity of factories where lead is manipulated has afforded Grawitz opportunity to study lead poisoning on an unusually extensive scale. He states that he never found any indications of hemocytolysis in these patients, no hemoglobinemia, icterus nor hemoglobinuria, and yet, they were distinguished by a grayish-yellow complexion and progressive anemia. The anemia resembles that which follows the gradual absorption from the intestines of toxins destructive for the blood. He also noted that a similar anemia is observed in patients with intestinal hemorrhages, or with hemorrhagic ulcer or carcinoma of the stomach, or intestinal hemorrhage accompanying cirrhosis of the liver. The red corpuscles in all these cases show granular degeneration at the time of the hemorrhages, disappearing soon afterward. He cites other data to support his assumption that this degeneration is the result of the formation of toxins in the intestines by the action of the bacteria of putrefaction on the masses of blood. He also succeeded in inducing this granular degeneration of the red corpuscles in healthy persons by administering to them various preparations of hemoglobin sold as tonics. The degeneration was apparent after a dozen pills of either "sanguinol" or "hæmol" had been taken, and it disappeared soon after the pills were suspended. There was no increase in the excretion of indican. These facts throw light on the degeneration of the blood in case of intestinal auto-intoxication in general, and on the anemia of ancylostomiasis. The anemia in the latter is due partially to the loss of blood sucked by the parasites in the intestines, and partially to the toxins generated by the putrefaction of the blood constantly trickling into the intestines.

**Removal Through the Mouth of Fishbone in Left Bronchus of Young Child.** J. A. KILLIAN.—A gill plate, 22 mm. long, was impacted in the left bronchus of a child three and one-half years old, as Killian determined by direct bronchoscopy. After chloroform and cocaineization of the throat—the little patient with head pendent—the bone was removed with a small hook, all under control of the eye through the bronchoscope, without injury to the air passages. In case this method of bronchoscopy does not succeed, or there is threatening stenosis, the bronchoscope could be introduced through a tracheotomy wound.

Wiener Klin. Wochenschrift, December 5.

**Sterility.** R. CHROBAK.—With the application of laminaria and tupelo Chrobak has cured a number of cases of sterility, characterized by slight hypoplasia of the uterus, scanty or irregular menstruation, sexual anesthesia and sterility. In other cases he has found it necessary to cut a wedge-shaped piece out of the internal os. This has no influence on the sexual anesthesia. Sterility is due in other cases to the immediate loss of the sperma from the vagina, either from relaxation of the parts or from forcible expulsion from an excessive contraction. Slackness of the part should be treated by general tonic measures and gymnastics of the levator ani and of all the muscles of the perineum, with, possibly, the shortening of the elastic muscles, pessary treatment, an insignificant plastic operation or paraffin prothesis. In case of a short vagina and retroversion, with sensitive adnexa, he slits the rear wall of the portio down to the posterior vaginal cul-de-sac and resects a wedge, as pessary treatment is inapplicable here. He considers loss of the sperma in such cases an indication for radical intervention.

December 26.

**Pigment Patches in Connection with Pernicious Anemia.** A. V. DECASTELLO.—The development of pernicious anemia may be preceded by several years by the development of patches of pigment, with hypertrophy or atrophy of the skin. The patches, in a case described, coincided with certain zones of sensory spinal innervation, demonstrating their dependence on some alteration of the central nervous apparatus. In some cases the patches appeared with the development of the anemia, or occurred during its course, and in one case that has been reported, appeared during a remission and retrogressed later. In the personal case described, the absence of all other sensory or vasomotor disturbances indicated that the cause of the pigmentation originated in the trophic centers and tracts.

**Peripheral Gangrene in Phosphorus Intoxication.** F. VOLLBRACHT.—Subacute intoxication with phosphorus disturbs the circulation to such an extent that the peripheral parts of the body have a tendency to gangrene. In three of the few rare cases that have been reported—including a personal case described at length—the aorta system was found abnormally narrow. This was evidently a favoring factor in the production of the gangrene, as was also compression of a part of the body in another case.

Zeitschrift f. Orthop. Chirurgie (Stuttgart), ix, 4.

**Joint Neurosis and Joint Neuralgia.** C. MOEHRING.—These two affections can be differentiated, Moehring states, by the character of the pains and by the tenderness of the nerve trunks of the region in the neuralgia. There is frequently in both a history of a preceding acute infectious disease. A joint neurosis is a combination of phenomena which indicate functional, traumatic or vasomotor disturbances or all associated. The joint is frequently intact to all appearances, or the trifling alterations are out of all proportion to the intense pain. It almost always grows less at night and allows the patients to sleep. The limb involved is remarkably weak, without the slightest atrophy of the muscles; in some cases the muscles and tendons are rigid, the limb usually in extension. Puncture and local treatment are ineffectual, but arsenic and potassium iodid or even quinin have produced good effects. The joint

neurosis affects principally, 1, hysterics; 2, persons with congenital or acquired weakness of the nervous system; 3, persons of a feeble constitution, and in a few instances, otherwise healthy persons. Both peripheral and central causes combine to induce a neurosis of this kind in most cases. When a trauma sets up a violent joint neurosis in an otherwise healthy person, some central disturbance of reflex origin probably exists in the lateral columns. It is possible that the local treatment instituted in these cases entails increased irritability of the nerves, on one hand, and prolongs the central disturbance on the other. Exercise of the joint would counteract this tendency, as an adjuvant to general tonic measures. In all cases of joint neurosis, an energetic psychic treatment is indispensable. The efforts of the physician are frequently supplemented by chance. A fright, an intercurrent affection, or an entertainment may be followed by the disappearance of the pains as suddenly as they commenced. Many of the "miracle cures" probably belong to this category. The physician should aim to prevent the development of such a condition in the predisposed under his charge. Moehring relates the details of ten cases personally observed, the patients being from 12 to 38 and more years old.

## Queries and Minor Notes.

VITAOPATHY AT ROCHESTER, N. Y.

SAN FRANCISCO, Dec. 6, 1901.

*To the Editor:*—Possibly the following may not be of interest to you, but I enclose it as one of the things the reorganized profession should fight. Mrs. L., of San Francisco, has a cancer of the pyloric end of the stomach. She is an emaciated woman with a decided cachexia, and with an abdominal wall so thin that the merest tyro could not do otherwise than made a diagnosis, for the outline of the tumor is perfectly evident to both palpation and inspection. I had occasion some months ago to diagnose her case, when I advised pylorotomy. The distinguished gentleman who is responsible for the enclosed letter evidently does not agree with me! G. H. E.

ROCHESTER, N. Y., U. S. A., Nov. 26, 1901.

*"Dear Mrs. L.:*—Your request for free diagnosis came duly to hand. I have given your case my careful consideration, also consulted with my specialists relative to it, and it is our combined opinion that you are suffering from myasthenia gastrica.

"These troubles, while not yielding to the ordinary forms of treatment, either magnetic, mental or medicinal, respond promptly to Vitaopathy. I have treated many cases exactly like yours. This method is original with me, being the result of years of study and experience. It is certain in its effects and never fails to bring about immediate and satisfactory results. My staff of specialists have spent years in treating such cases as yours in the ordinary practice of medicine. They are now devoting their entire time to the application of Vitaopathy to such cases, and the results are truly marvelous.

"If you allow me to take up the treatment of your case, I will do so with every confidence of effecting a final cure. I have hundreds of similar cases under treatment, all testifying to the marvelous benefits received. As a reasonable person, you know that with the experience gained in treating so many similar cases, it is natural for me to understand such better than the ordinary physician who, perhaps, has only a few cases each year. 'Practice makes perfect,' and it applies to the treatment of diseases as well as any other line. The more we practice the more we learn, and the larger percentage of cures we make. I have the advantage of treating tens of thousands annually, while the ordinary physician treats but a few hundred. Remember, that my treatment is especially prepared for each individual case. If you went to specialists, such as I have in my employ, they would charge you from \$10 to \$20 for an examination. I give you the attention of these specialists free. They have made a life study of certain diseases which their specialty covers, and if you place your case in my hands, it will have the very best attention that recognized specialists can give it. They will study your case continually and offer suggestions which will aid the treatment in curing you in the shortest possible space of time.

"For financial responsibility, honesty and integrity, I refer you to the Flour City National Bank, of this city. For an immediate reference relative to the treatment, I invite you to write to Rev. Joseph Mills, Mankato, Kan., also to D. L. d'Elysee, Notary Public of Samoath, Ill. I shall be pleased to furnish other references if you desire them. At the low rate I charge you can not afford to be without this treatment—without all the expert attention I give you. If the druggists in your city were able to fill the prescriptions which I have filled for you at my laboratory, their price for the remedies, alone, would be more than I ask for the entire treatment. The cost of treatment is \$5 per month. Is there a physician in your city who could afford to treat you at this rate, giving you treatments twice a day as I do? Certainly there is not, and I am

enabled to do this only because I treat so many cases that I can keep my specialists profitably employed all the time.

"You can not afford to miss this opportunity. Remember that I have cured hundreds of cases that have been regarded as hopeless, cured them after all other methods had failed. Whether you take my treatment or not, I should like to hear from you. I will be glad to correspond with you relative to your case. I have the interest of humanity at heart aside from any financial consideration.

"If you will order a month's treatment within fifteen days from the date of this letter, I will give you my new course of instruction in Magnetic Healing absolutely free. The price of this course is \$3. In order to introduce it in your community I have decided to give it to you free of charge. All I ask in return is, for you to recommend it to your friends whom you think might be interested. It is the best course in magnetic healing on the market. I guarantee this. I am sure you will be greatly pleased with it. I should like to hear from you by return mail, so that I may know you have received this communication.

"Institute of Physicians and Surgeons

"THOMAS F. ADKIN, President."

The letter quoted above is ornamented with a fine pictured letter head, with the following artistically printed: "Prof. Thomas F. Adkin, Pres., Originator of the Adkin Viteopathic Treatment; L. H. Hawley, M.D., Chief Consulting Surgeon and Expert Diagnostician; Prof. S. A. Newman, Chief Chemist; Prof. Chas. B. Westover, Secretary and Clinical Director. New York Institute of Physicians and Surgeons and the Thomas F. Adkin Sanatorium. Chartered by the State of New York. Address all communications relative to treatment to Thomas F. Adkin, Pres. Paid up Capital \$50,000.00. All Human Diseases Successfully Treated by the Adkin Method."—Editor.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant General's Office, Washington, D. C., Dec. 26, 1901, to Jan. 8, 1902:

James T. Arwine, contract surgeon, from Fort Lisicum, Alaska, to San Francisco, Cal., for assignment in the Department of California.

Dallas Bache, colonel, assistant surgeon-general, retired Jan. 1, 1902, at his own request, he having served more than forty years.

David Baker, lieutenant, asst.-surgeon, U. S. A., previous orders so amended as to direct him to report for duty to the commanding officer, Fort Leavenworth, Kan.

Cosum J. Bartlett, lieutenant, asst.-surgeon, U. S. A., from the general Hospital, Presidio of San Francisco, Cal., to Fort Lisicum, Alaska.

Robert C. Eve, contract surgeon, from Fort Sam Houston, Tex., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Charles R. Ewing, major, surgeon, U. S. A., from New York City to Fort Preble, Me.

Peter C. Field, lieutenant, asst.-surgeon, U. S. A., from Fort Slocum, N. Y., to Fort Robinson, Neb., for duty at that post.

Ernest W. Fowler, contract surgeon, from Fort Preble, Me., to Fort Terry, N. Y.

Joseph C. Garlington, contract surgeon, from Fort Terry, N. Y., to San Francisco, Cal., en route to the Division of the Philippines.

Charles R. Greenleaf, colonel, assistant surgeon-general, retired Jan. 1, 1902, under the operation of law, he having attained the age of 64 years.

John T. Halseell, contract surgeon, relieved from further duty in the Division of the Philippines and from temporary duty in the General Hospital, Presidio of San Francisco, Cal., for assignment at Fort Sam Houston, Tex.

Thomas Howlett, contract surgeon, from Gilroy, Cal., to San Francisco, Cal., en route to duty in the Division of the Philippines.

Edward H. Jordan, contract surgeon, from Denver, Colo., to San Francisco, Cal., en route to duty in the Division of the Philippines.

Charles F. Kleffer, captain, asst.-surgeon, U. S. A., from duty in the Division of the Philippines to San Francisco, Cal., whence he will report by telegraph to the Adjutant-General of the Army for further orders.

John F. Leeper, contract surgeon, previous orders so amended as to assign him to temporary duty in the Department of California.

Marlon F. Marvin, contract surgeon, from Jacksonville, Fla., to San Francisco, Cal., en route to the Division of the Philippines.

Charles F. de May, captain, asst.-surgeon, Vols., leave of absence for one month granted.

Frank D. Pease, captain, asst.-surgeon, Vols., leave of absence granted to Jan. 31, 1902, on account of sickness.

William H. Pomeroy, contract surgeon, now at Springfield, Mass., to duty at Springfield Armory, Mass.

David S. Roberts, contract surgeon, member of an examining board at San Antonio, Tex., during the illness of Colonel P. J. A. Cleary, assistant surgeon-general.

Albert H. Simonton, contract surgeon, from Fort Robinson, Neb., to Birmingham, Ala., for annulment of contract.

Albert E. Truby, lieutenant, asst.-surgeon, U. S. A., leave of absence extended.

Harry H. Van Kirk, contract surgeon, from Washington, D. C., to his home at Sunbury, Ohio, for annulment of contract.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ended January 11:

P. A. Surgeon W. B. Grove, ordered to the *San Francisco*.

P. A. Surgeon W. C. Hralsted, detached from the *Topeka*, and ordered to the Naval Hospital, New York.

Asst.-Surgeon P. M. Furlong, ordered to Vicksburg, Miss., for duty with recruiting rendezvous; and upon completion of that duty, proceed to the *Topeka*.

Asst.-Surgeon E. O. Huntington, detached from the *Columbia* and ordered to the Naval Hospital, New York.

Asst.-Surgeon F. I. Benton, detached from the Naval Hospital, New York and ordered to the *Columbia*.

Surgeon C. F. Stokes, detached from the *Solace*, and ordered to duty at Guam, I. I.

Surgeon F. A. Healer, ordered to remain on duty on the *Asiatic* Station.

Medical Inspector W. A. McClurg, detached from the U. S. T. S. *Constellation*, and ordered home to hold himself in readiness for sea duty.

Medical Inspector J. R. Waggener, ordered to the U. S. T. S. *Constellation*.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the 7 days ended Jan. 9, 1902:

Surgeon Fairfax Irwin, bureau telegram of Dec. 27, 1901, granting leave of absence for seven days, amended so that said leave shall be for five days.

Surgeon H. R. Carter, leave of absence for ten days granted, by Bureau letter of Dec. 26, 1901, revoked.

Surgeon P. C. Kallioch, to proceed to Portland, Me., and assume charge of the quarantine service at that port.

Surgeon J. J. Kinyoun, six days' leave of absence from Jan. 6, 1902, under paragraph 179 of the regulations.

A. A. Surgeon E. F. McConnell, granted leave of absence for thirty days from December 24.

A. A. Surgeon J. N. Maceo, granted leave of absence for thirty days from December 17.

A. A. Surgeon C. F. Hildeout, granted leave of absence for ten days from January 2.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended January 11, 1902:

#### SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 22-29, 2 cases.

Indiana: Evansville, Dec. 22-Jan. 4, 3 cases.

Iowa: Clinton, Dec. 27-Jan. 4, 1 case.

Louisiana: New Orleans, Dec. 27-Jan. 4, 1 case.

Massachusetts: Blackstone, Jan. 1-8, 2 cases; Boston, Dec. 27-Jan. 4, 21 cases, 6 deaths; Brockton, Dec. 27-Jan. 4, 1 case; Cambridge, Dec. 27-Jan. 4, 2 cases; Chelsea, Dec. 27-Jan. 4, 1 case;

Lowell, Dec. 27-Jan. 4, 4 cases; Medford, Dec. 27-Jan. 4, 2 cases; Newton, Dec. 27-Jan. 4, 1 case; Quincy, Dec. 27-Jan. 4, 1 case;

Somerville, Dec. 27-Jan. 4, 1 case.

Nebraska: Omaha, Dec. 27-Jan. 4, 29 cases.

New Hampshire: Nashua, Dec. 27-Jan. 4, 2 cases.

New Jersey: Camden, Dec. 27-Jan. 4, 19 cases; Jersey City, Dec. 22-29, 1 death; Newark, Dec. 27-Jan. 4, 31 cases, 1 death.

New York: New York, Dec. 27-Jan. 4, 8 cases, 2 deaths.

Ohio: Cincinnati, Dec. 28-Jan. 3, 9 cases; Cleveland, Dec. 27-Jan. 4, 1 case; Youngstown, Dec. 21-28, 1 case.

Pennsylvania: Dec. 27-Jan. 4, Allegheny, 2 cases; Norristown, 1 case, 1 death; Philadelphia, 90 cases, 16 deaths.

South Carolina: Greenville, Dec. 27-Jan. 4, 1 case.

Tennessee: Memphis, Dec. 27-Jan. 4, 2 cases.

Vermont: Burlington, Dec. 21-28, 30 cases.

Virginia: Roanoke, Dec. 24-31, 41 cases.

Washington: Tacoma, Dec. 22-29, 2 cases.

Wisconsin: Green Bay, Dec. 29-Jan. 5, 5 cases, 1 death; Milwaukee, Dec. 29-Jan. 4, 1 case.

#### SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Oct. 1-31, 61 deaths.

Austria: Prague, Dec. 7-14, 16 cases.

Belgium: Antwerp, Dec. 7-21, 4 cases, 1 death; Ghent, Dec. 14-21, 4 cases.

Brazil: Rio de Janeiro, Nov. 28-Dec. 8, 83 deaths.

Canada: Halifax, Nov. 22-Jan. 4, 15 cases; Quebec, Dec. 28-Jan. 4, 21 cases.

Colombia: Cartagena, Dec. 16-22, 3 deaths.

France: Paris, Dec. 14-21, 6 deaths.

Great Britain: Liverpool, Dec. 7-21, 3 cases; London, Dec. 14-21, 538 cases, 32 deaths.

India: Calcutta, Nov. 23-Dec. 7, 2 deaths; Madras, Nov. 23-Dec. 6, 3 deaths.

Italy: Naples, Dec. 7-14, 16 cases, 1 death.

Russia: Odessa, Dec. 7-14, 3 cases, 1 death; St. Petersburg, Dec. 7-14, 5 cases, 1 death.

Spain: Corunna, Dec. 14-21, 2 deaths.

Uruguay: Montevideo, Oct. 25-Dec. 9, 108 cases, 5 deaths.

#### YELLOW FEVER.

Brazil: Bahia, Nov. 30, Dec. 7, 1 case, 1 death; Rio de Janeiro, Nov. 25-Dec. 8, 4 deaths.

Mexico: Vera Cruz, Dec. 21-28, 6 cases, 2 deaths.

West Indies: Saint Lucia, Dec. 9, prevalent.

#### CHOLERA.

India: Bombay, Nov. 26-Dec. 3, 5 deaths; Calcutta, Nov. 23-Dec. 7, 79 deaths.

Java: Batavia, Nov. 8-30, 40 cases, 28 deaths.

#### PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Nov. 23-Dec. 5, 11 deaths.

India: Bombay, Nov. 23-Dec. 10, 238 deaths; Calcutta, Nov. 23-Dec. 7, 50 deaths; Karachi, Nov. 23-Dec. 8, 169 cases, 155 deaths.

Mauritius: Dec. 5-12, 42 cases, 25 deaths.

Russia: Batoum, Dec. 12, 1 case, suspect.

South Africa: Port Elizabeth, Nov. 30-Dec. 7, 1 case; Massell Bay, Nov. 30-Dec. 7, 2 cases.

### INDICATIONS FOR AND UTILITY OF ALTI- TUDE TREATMENT IN PULMONARY TUBERCULOSIS.\*

S. E. SOLLY, M.D.

COLORADO SPRINGS.

It is especially useful at the present time to be reminded of what is known of the effects of high climates, because the excitement produced in many physicians by their reception of the idea that the open air, forced feeding and sanatorium treatment are of immense value in arresting phthisis, has caused them, in their eagerness to use these, to them new weapons, to inconsiderately fling away many a proven weapon of the past.

#### INFLUENCE OF ALTITUDE.

In the consideration of the influence of altitude there are two important matters to be recognized—the physical conditions of the climate and its physiologic effects. The essential distinction of the climate at a high altitude from that at a low level is the diminished barometric pressure. The most notable and important of the permanent effects of this reduced pressure is the influence it exercises on the blood, in producing an increase of red cells and hemoglobin.

While the question is still *sub judice*, I believe the evidence up to date indicates that the increase is an actual total increase of the bulk of the red cells and hemoglobin, and not merely a calling forth of stored-up supplies from the abdominal organs or elsewhere, nor a mere inspissation of blood due to the excessive dryness of the mountain air. I can not further pursue this topic on the present occasion, but would refer you to a study of the experimental work that has been done, especially that of Drs. Schaumann and Rosenquist of Helsingfors.

By what exact process these conditions are produced is still undetermined; nevertheless, the clinical fact remains, that suitable cases of anemia, transported to an altitude, are quickly cured, apparently in a similar way that they may be by the administration of iron, which result in the latter case would seem to be brought about not so much by directly adding the required quantity of iron to the blood, as by the stimulus given to the action of the blood which enables it to absorb its necessary amount of iron from the food once more, as in health.

The effects of altitude on the circulation and respiration are both temporary and permanent. The immediate effect is to increase the rapidity of the heart's action. This rapidity is quickly modified, at least while the visitor is in repose, and during the first four weeks the heart's action gradually becomes once more normal. The blood pressure, which at first is raised, later is permanently lowered. That diminished air pressure will alone produce lowered blood pressure has been abundantly proved by laboratory experiments. In dealing with the cardiac complications that arise in tuberculous subjects, this effect of altitude must be reckoned with.

The immediate influence of altitude on the respiration is to increase the rapidity of the respiratory wave, but this also quickly returns to the normal rate, at least in healthy persons. By exertion the respiration and the rate of the pulse are both increased, not so much in the natives or in persons long resident in high altitudes, as in the case of visitors, in whom they are temporarily more rapid than at the sea level.

The permanent effect of the diminished barometric pressure on the lungs is to increase the depth of the respiration and to expand the air cells so that in children a normal condition resembling emphysema is brought about.

Moreover, the total capacity of the thorax is increased. These effects have been proved by many observations, notably by those of two physicians in the city of Mexico, Drs. Herrera and Lope, who found that the chest measurements of visitors were increased at high elevations, and that those of natives and permanent residents were greater than the average measurements of persons living at sea level. In their valuable book entitled, "La Vie sur les hauts Plateaux," the details are given of numerous measurements of various parts of the bodies of natives, particularly of their chests, and they are compared with similar measurements of natives of countries situated at sea level. Besides these there are detailed many interesting studies of animal and plant life on the high plateaus.

Of course, the extent of this increase in chest capacity in visitors from the lower countries is largely dependent on their youth and the elasticity of their thoraces.

Some interesting experiments by Robin and Binet are recently reported which appear to prove that, contrary to the previous belief, more oxygen is taken in by the consumptive than by the normal man. Up to the present time this statement, however, has not been tested and accepted by other observers; thus we do not know positively whether the diminished oxygen pressure to which a man is subjected on his transportation to a high plateau or mountain is of advantage to him, either directly or indirectly. It is possible that the diminished amount of oxygen may be of benefit by lessening the

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

burning up of tissue apart from the effect it is believed to have in causing increased respiratory action.

As a consequence of the dryness of the air in high climates there is more evaporation from the lungs and skin, and a lessened loss of water through the kidneys and bowels. The amount of water excreted and evaporated from the body, however, after a time becomes normal. But on the first arrival of patients at high altitudes it is customary to find that there is a greater amount of solids in the urine than under ordinary circumstances at lower levels, which is doubtless due to this increased evaporation from the lungs which occurs during all seasons and from the skin also when the air is warm.

The beneficial effects of sunlight are very marked on various diseases; and at high altitudes sunlight is very abundant, prolonged and intense. Generally speaking, it is healthful, though too exciting and irritating for some patients.

The question of air temperature is always of great importance; it varies, of course, at different altitudes, but at all altitudes there are found in varying degrees cool nights and warm days, with cool air and warm sunshine. The old idea was that for a climate to be beneficial, especially for the phthisical, it must be equable. Now, however, it is recognized that the great change of temperature, from day to night, is of the greatest value to many invalids, its action on the body being very much the same as a cold douche following a hot bath. It has undoubtedly much the same effect that cold bathing has in typhoid fever; it braces the nervous system and stimulates the nutritive processes.

The aseptic condition of the air is also of importance. At most altitude resorts there are few dwellings, few crops and the population is sparse; so for these reasons the air is pure, which is obviously an advantage.

These are the main points in regard to the influence which altitude exercises therapeutically. There are, however, different degrees and kinds of altitudes. These may be divided into three classes: Cold, warm and hot. The difference in this respect, while dependent in a measure upon latitude, is still more largely a matter of altitude. As a rule the higher the elevation the cooler is the atmosphere. But this rule is modified in accordance with the position of the altitude in relation to the equator. For instance, the Swiss Alps are colder than the same altitude in Colorado. When it is thought desirable to modify the temperature it is generally necessary, in order to do this, to change the altitude. The two things usually go together. The configuration of the ground is also of importance, that is, its topography has to be taken into account, namely, whether a place is situated in a valley, on a plateau or on the side of a mountain, and whether the natural as well as the artificial drainage is good.

#### AMERICAN AND SWISS CLIMATES.

Speaking broadly of the matter of temperature and altitude, it may be said that on this continent we find the more extremely cold elevations in Canada, although they have so far been but little used, but in these regions are places that compare favorably in climate though not in resources with some of the most frequented resorts of the Swiss Alps. On the other hand, there are ready and much used the lower elevations and warmer climates of Arizona and New Mexico; and between them are the varying altitudes and medium temperatures of Colorado.

As the cold regions this side of the Atlantic have not

been much frequented by invalids, we must go to Europe for the purposes of comparison. The Alps have the disadvantage of limited hours of sunshine, while they have the advantage of less wind and dust. At the other end of the pole take Arizona. It has the advantage, for some patients at least, of increased warmth and moderate elevation, coupled with great dryness and no great variations of weather. At the same time it has the disadvantage of having more dust and the more enervating conditions which come with heat. Colorado, as has been said, lies between the two.

In the Swiss Alps the summers are very pleasant, although the winters are usually preferable for the treatment of tuberculous patients. For persons in ordinary health the summers at the altitudes are admirable, but they are more rainy than the winters, and tuberculous patients do not seem to do so well as in the latter season. In Arizona the heat is too great in the summer to make it wise to leave most patients there at that season; although some undoubtedly thrive under the parching heat. In the resorts of Colorado is found something intermediate between the two. In the latter there is a winter climate which is more suitable for outdoor life than the sheltered parts of colder regions; but at the same time there is more wind and greater range of temperature. It is not suited to advanced cases or to enfeebled persons who can not take exercise. For young, vigorous persons, and in fact for all who can spend a large portion of their time out of doors, and who can take moderate exercise, an immense advantage will be found to arise from these very changes in the temperature.

#### CLASSIFICATION OF PATIENTS.

As to the classes of patients who should be sent to high altitudes, many things have to be carefully considered. The first matter to be inquired into is: Why did the patient become tuberculous? Although the bacillus is the central fact in the process of tuberculosis, the germ behaves differently in different persons, and the disease may arise from different predisposing causes. Apart from the introduction of the bacillus the general condition of the patient's health is of importance.

Tuberculous patients may be divided for the sake of convenience into three classes: The purely tuberculous, the catarrhal and the pneumonic. Of course these terms are subject to mis-understanding and abuse, because all these patients are ultimately tuberculous and there is present in each more or less catarrh or inflammation; nevertheless, I have found the division on the whole the most convenient for use. The important thing is to distinguish between cases that can be traced to definite causes and those cases in which the tuberculosis has arisen without any apparent cause, coming like lightning out of a clear sky. Such may be regarded as original cases of tuberculosis; these as a rule do well in a climate like that of Colorado. They need a stimulus, and when handled with discretion are generally benefited more markedly by the altitude treatment than by any other therapeutic measure, climatic or otherwise, provided the general hygienic care is equally good. Catarrhal cases—those subject to catarrhal conditions of the respiratory tract on slight cause—have generally behind them some fault in the metabolism; there are usually also existing in such patients deficiencies of construction which make them more liable to these attacks. They are particularly susceptible to weather, more especially changeable weather. Therefore, you have to be very careful with them in climates like Colo-

rado, and the majority do better in the equally dry but warmer and less elevated climates of New Mexico and Arizona. Then there are the pneumonic cases—those in whom there is considerable febrile reaction to the disease and in whom an inflammatory process has been set up. Cases of this kind are not so well suited to the higher ground. The air is apt to be too stimulating for them. They usually improve more satisfactorily lower down and in a moister air. Of course, all of these cases come to us more or less mixed, but my experience is, that if you can trace the history of your patient you will generally find something to guide you in caring for the case. Therefore, I consider that the taking of the history of the patient is of great value in shaping his treatment.

The mental condition of the patient must also be taken into account in sending him away from home. The possibility of his being affected by homesickness must be considered. It is important, therefore, to know something about the habits of your patient. For example, a person who never enjoys traveling, and is always longing for his own fireside, is far better left at home, unless you can arouse his attention towards his new surroundings and contrive to make them interesting to him. I remember one man who could not get well in Colorado because he pined for his unhealthy life in Philadelphia and sadly missed, he quaintly said, "even the stink of the all-pervading gas." On the other hand, there are those who enjoy the change. In all therapeutic measures change of mental attitude is an important factor, but you can not hope to do anything to influence it unless you understand your patient.

The question of social condition is likewise important. It may be said that there are three classes of patients: The rich, the comparatively well-to-do, and the poor and laboring class. The rich are benefited as a rule by being sent to higher altitudes, other conditions being appropriate, because this is generally the greatest change that can be given them. They have presumably been living under good hygienic conditions, and the greater the change climatically they can be given, the greater is likely to be the effect on mind and body. With the well-to-do, who are accustomed to be continually occupied, it is sometimes a serious question whether it is desirable to put them in a place where they can have no occupation. It is important that the physician should direct their minds into new channels of thought and give them new ways of occupying their time. I do not mean necessarily remunerative ones, but something that will occupy their time while it excites their interest and makes them happy and comfortable. Among the poorer class of patients, those who have been used to labor out of doors, will generally be found to do better than those who have followed indoor occupations. The former can generally be set to some work that will keep them interested. The indoor laborers are more difficult to deal with and the outlook for their recovery is not as encouraging. Still, they are not, for these reasons, necessarily barred from altitude treatment.

Other matters which must be considered before the decision is made to send a patient away from home for climatic change, are the special symptoms of the disease and the stage to which it has advanced. Physicians at altitudes, like their confrères in all other resorts, always demand that patients should be sent to them at the earliest possible stage. While this condition is always to be preferred, removal to an altitude need not necessarily be made at an early stage.

There is no reason why cavity cases of moderate extent and even of long standing should not go to altitudes, other conditions being suitable; but all cases which are deteriorating rapidly ought to be first treated like hospital patients suffering from any other acute disease. Afterwards certain of such cases can be sent to an altitude with much advantage.

Hemoptysis is not necessarily a bar. At the recent meeting of the American Climatological Association at Niagara Falls, Dr. Bonney, of Denver, read an important paper in which he confirmed the conclusions that several of us had arrived at from our own observations, viz., that hemorrhage cases do no worse at an altitude than elsewhere and probably better, and that the fact of their bleeding is not of itself an argument against sending them to a high climate. Another important thing is for physicians at home to study their cases thoroughly before sending them away for climatic change. In this connection I think the state institutions and other home sanatoria that are now springing up everywhere will be of immense value. From these institutions we may expect to have more and more well-selected cases sent to high altitudes with the greater certainty of good results.

Finally, let us remember the oft-quoted dictum that it is not only the individual sickness we have to consider, but also the sick individual.

#### ADAPTABILITY OF SOUTHERN CALIFORNIA AND SIMILAR CLIMATES TO THE NEEDS OF CONSUMPTIVES.\*

NORMAN BRIDGE, A.M., M.D.

LOS ANGELES, CAL.

When we speak of Southern California as a climate, or a place to live, we usually mean that part of the country lying between the ocean and a range of mountains forming an irregular semicircle and extending from a point near to and north of Santa Barbara to a point some miles back of San Diego. We do not mean the Colorado desert lying east of this mountain range, nor the Mojave desert north of it, although they are both geographically in Southern California.

The climate, then, of Southern California is, to some degree, adaptable for consumptives because it has: 1. relative dryness; 2. small rainfall; 3. large degree of sunshine; 4. low and high altitudes; 5. mildness of climate throughout the year, permitting outdoor life; 6. low barometer range, and finally, 7. a good record in tuberculous cases. These conditions are generally regarded as important for consumptives. They all probably have advantages, although some of these are wrongly explained and some overestimated.

For example, dryness is supposed to be beneficial by reducing expectoration. For this reason it is probably actually harmful, by increasing the retention and tenacity of the expectoration. It can not be harmful to have enough moisture in phlegm to cause it to be easily moved through tubes, and excessive dryness prevents this. Dryness is valuable, because it lessens the cough and so increases the quiescence of the lung tissue, which is a consideration of the greatest possible importance. A moist climate is thought by many to be very injurious to consumptives, yet many cases recover at San Diego and

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon, and N. S. Davis, Jr.

Santa Barbara, both on the Pacific coast, and also in the Sandwich Islands, surrounded by the ocean, as well as on shipboard at sea.

High altitudes doubtless help some consumptives, but not by expanding the air vesicles of the diseased tissue. This is harmful and ought to be discouraged. The value must be in the effect on the red corpuscles, and some of the other and cognate changes in the physiologic conditions and forces. Low altitudes give more oxygen in the air breathed and less perturbation from low barometric pressure than high ones do.

The air in Southern California is relatively dry as compared with the middle and eastern parts of the country. The driest region is, of course, farthest from the coast. The mean relative humidity is, by comparison with other representative places, as follows, expressed in percentages of saturation: Chicago, 72; Denver, 53; San Diego, 69; Los Angeles, 66; Southern California foothills (Pasadena to Redlands and Riverside), 64.4 to 65; Yuma, 46, and Prescott, 71.

The record of the actual amount of water dissolved in the air of these places, by comparison with the relative dryness, presents what at first seems to be a puzzle. What is relatively dry may be actually moist. It is rational enough, however, when we consider the laws of meteorology; and it shows how our calculations in the management of the sick are based wholly on the relative and not the actual dryness of the air.

We find that the mean amounts of water in the air of the places named—expressed in grains of water to the cubic foot of air—are as follows: Chicago, 2.80; Denver, 2.11; San Diego, 4.19; Los Angeles, 4.00; foothills, unrecorded; Yuma, 4.12, and Prescott, 2.20.

Thus Prescott, which has the highest relative moisture of all the places given—74 per cent. of saturation—has a very small degree of real humidity; and Yuma, which has the lowest relative humidity, carries more water per cubic foot of air than Los Angeles or Chicago, and almost as much as San Diego.

The rainfall record shows Southern California to have a small amount of precipitation. The rains come mostly from December to April inclusive. The number of days of falling weather are, even through these months, fewer than in the East. The annual rainfall in Los Angeles and the average of the eastern foothills—Redlands, Riverside and San Bernardino—is 15 inches. This is the same as at Denver, while the western foothills—Sierra Madre, Pasadena—have 16 inches, and San Diego has but 10 inches.

The relative degree of cloudiness and sunshine is usually reckoned as an element in the general question of humidity. It is more an element in the mildness of a climate. The mean percentages of cloudiness by day of the places named are as follows: Chicago, 51; Denver, 38; San Diego, 42; Los Angeles, 34; western foothills, 30; eastern foothills, 28.9; Prescott, 24, and Yuma, 17.

The altitudes of Southern California are mostly low, from sea level to 1500 feet at the foothills near the mountains. If low altitudes are unadapted to consumptives, then these regions are objectionable. Los Angeles has an elevation of 300 feet; Pasadena, 800; Sierra Madre, Altadena, Redlands, Riverside and the Ojai valley from 1000 to 1500 feet. But there are regions of high altitude where patients are often sent for variable periods, with more or less benefit. One of these is the mountain resorts back of Pasadena, including Wilson's Peak, Echo Mountain and Alpine Tavern, whose altitudes vary from 3500 to 6000 feet. Another place that

has been a resort for a few patients for many years is Strawberry Valley, in the San Jacinto mountains, lying southeast from Riverside and being on the divide between the coast plateau to the west and the Colorado desert to the east; it looks down upon Indio and is the dry desert resort for consumptives. The elevation of Strawberry Valley is 5000 feet. This is an ideal place for the sick, but has the disadvantage that it is reached only by a stage ride of twenty miles from San Jacinto station on the Santa Fe railway. A powerful and speedy automobile service has been introduced, and it is hoped will make this journey much less objectionable.

The weather in Strawberry Valley is much like that of the mountains of Colorado, with occasional showers during the summer and some snow in the winter; the temperature ranges from 20 degrees on the coldest nights of winter to 85 or 90 in midday of the hottest days of summer. The scenery reminds one of the White Mountains of New Hampshire. The California Health Resort Company, Los Angeles, has acquired a large tract of land in this valley and has just finished the construction of a sanatorium which will accommodate a large number of patients, whom it is expected, will be mostly of the tuberculous class. The plans and regulations of the company indicate a sanatorium on the plan of those of Sharon and Rutland in Massachusetts, and of the better class of those of Europe. So much money has been invested in the enterprise that the company can not afford to drop in its standard of management, and it is promised to the profession that in the care of the patients the directions and wishes of the attending physicians who send patients shall be carried out in their management as far as possible, consistent with certain definite rules of the institution as to fresh air, outdoor life, supervision of exercise, rest and amusements, as well as the dietary and feeding. The water supply of the place is perfect and in the construction of the sanatorium every provision known to good hygiene seems to have been carried out.

The one quality in which the climate of Southern California is pre-eminent is its mildness and the ease with which one can live out of doors most of the time, both day and night, and during all seasons of the year. A dozen days of rain and as many of high wind are about all that need keep any patient wholly indoors, and, even in these days, he may have perfect ventilation of his room. There is nearly every day a breeze from the ocean during the day and one down from the mountains at night.

Occasionally, on a winter's night, the temperature drops for an hour or two slightly below freezing point, and during most of the days of winter and many of those of spring warm wraps and overcoats are acceptable at all times of the day. The warmer days of summer are, from 10 to 5 o'clock, sometimes very warm as shown by the thermometer, the temperature ranging from 85 at the coast to 102 at the eastern foothills—those farthest from the ocean; but to the human body properly clothed these temperatures are never experienced. With thin and light-colored clothes and hat, you would guess any day that a temperature of 100 was 85 or 90. Within twenty or thirty miles of the coast invalids are rarely uncomfortable from heat in summer even for an hour. The diathermancy of the atmosphere, due to dryness, especially some miles inland from the coast, is so great—particularly in summer-time—that the sensible as well as the real temperature of the air drops quickly as soon as the sun goes out of sight, whether under a cloud or at night. This fact makes it necessary to change one's clothing or

wraps much more often than is necessary in the East.

Mean temperatures are somewhat unenlightening as to the question of physical comfort at times of extreme fluctuations, but they are worth considerable by comparison. Mean temperatures of summer and winter are shown by the following table:

|                         | Summer. | Winter. |
|-------------------------|---------|---------|
| Chicago .....           | 68      | 22      |
| Denver .....            | 69      | 29      |
| Prescott .....          | 70      | 37      |
| Yuma .....              | 90      | 55      |
| Los Angeles .....       | 69      | 54      |
| San Diego .....         | 68      | 54      |
| Eastern foothills ..... | 75.3    | 54.7    |
| Western foothills ..... | 71      | 52.6    |

I can not doubt that the slight fluctuation of the barometer in Southern California is an advantage to the sick. The fluctuations in the barometer in Southern California are not more than half what they are in the eastern part of the country. A daily journey up and down a mountain gives one fluctuations in the barometric pressure, and such an exercise is not thought to be harmful. But a sudden drop in the pressure will often give one a neuralgic or so-called rheumatic pain and disagreeable and depressed feelings. Some evidence has been accumulated in the past to show that at times of low barometer patients recover less rapidly and bear surgical operations less well. Fluctuations in air pressure are of doubtful value in any sickness unless prescribed for the particular case.

Finally, the experience of the past is valuable and beyond controversy. A large number of patients have recovered from tuberculosis in Southern California and have remained for many years with all the appearances of health. How large a proportion of those who have gone there with the disease have recovered nobody can tell. That this climate is better for consumption than some others in the United States, I would not pretend to say. But I know that experience has proved its great value, and the experience has justified the theory that most of the climatic benefit that ever comes to this pathetic class of patients is due to their ability to live practically out of doors a large part of the time, night and day. This is a doctrine, too, that to my mind has the support of common sense.

#### NINETEEN YEARS' EXPERIENCE WITH CREOSOTE IN TUBERCULOSIS.\*

JAMES A. BURROUGHS, M.D.

ASHEVILLE, N. C.

The general who has a difficult battle in contemplation not only surveys the ground and counts his men, but selects his best gun and places it at advantageous points, where it will not only offer the greatest protection to his men, but do its most effectual carnage to the enemy. Other things being equal, success or failure in the treatment of pulmonary tuberculosis depends largely upon a judicious selection and proper administration of creosote.

Being located as I am, at a point where a very large number of tubercular patients are directed by the best physicians of the country, I have a good opportunity to obtain a fairly correct opinion of the profession's confidence in creosote. My records for the past nineteen years, of 2183 cases of tuberculosis, scattered from all

points of the United States and the provinces of Canada, show that thirteen out of every fifteen patients were either taking creosote or had had it prescribed. These statistics are of value in arriving at a consensus of opinion of the profession to-day, when we observe that for the last seven years of this record, embracing more than one-half of the cases, seventeen out of eighteen were either taking creosote or had had it prescribed.

Much of the prejudice of the laity and disappointment to the physician in the use of creosote is due to the administration of an impure article. While it is noted that the bulk and file of these unfortunates are taking creosote, it is observed that so little attention is paid to its purity that many are getting nothing short of carbolic acid or a true wood product. No plain beechwood or any other wood creosote should ever be administered by stomach or applied locally. Creosote made by a double distillation from beechwood tar is practically free from carbolic acid and all other impurities; it possesses the greatest antiseptic and germicidal properties, and at the same time there is an absence of all nauseating, irritating and escharotic effect.

Mr. Thomas Morson's test is simple and satisfactory. It consists in the solvent power of glycerin over carbolic acid, which is dissolved by it in all proportions, while pure creosote is insoluble in glycerin, or nearly so, while carbolic acid is dissolved by it in all proportions. Consequently, if any liquid assumed to be creosote dissolves largely in glycerin it probably consists in whole or in large part of carbolic acid.

Creosote made by the double distillation of tar from beechwood, complying with the Morson test, can be administered in enormously large doses in the most delicate stomach, with decided clinical success. Rarely do patients come under my care who are taking more than 5 to 10 minims, which is certainly too small a quantity to be of decided value in the management of the tubercular; these small doses do a little good where there exists a feeble digestive apparatus, by partially preventing fermentation and thereby assisting digestion, but beyond this, in these small doses any beneficial effect upon the course of the disease is highly improbable. It is only in the large doses of creosote, from 60 to 100 minims three times daily by the mouth, and a local application to the lungs of 15 to 20 minims daily, that we recognize in this drug a well-nigh specific influence in pulmonary tuberculosis.

Creosote is best administered in either cod-liver oil, whisky or cream. Manufacturing druggists in recent years have a fad of combining creosote with many of their wares; it goes without comment that these preparations are of but little benefit, as the quantity of creosote is insufficient and quality questionable. Creosote should never be administered in capsules unless combined with an oil, and then the bulk or number of capsules would be objectionable. I have systematically used creosote subcutaneously in tubercular subjects, without observing any advantage over administering by stomach. One part of creosote to two of oil of sweet almond was the strength used, and in no instance have these injections given trouble. This mode of administering is sometimes admissible when a concentrated local effect of the drug is desirable or where there exists an idiosyncrasy or aversion by mouth.

In all cases of laryngeal and pulmonary tuberculosis, 20 to 25 minims of creosote in some hydrocarbon oil can and should be forced down into the lungs daily.

The drug must always be administered on a full

\*Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

stomach three times daily, commencing with 20 minims and increasing 1 minim daily until 60 is reached. Hold the dose at this point for one month, then drop back to 40 minims and start up again until 80 minims are reached, holding at this dose for a time. The process is repeated again when 100 minims or even more is reached and the patient held at this point for months or years, in the discretion of the physician. Rarely do I consider it safe for a patient to stop creosote until at least two years after all symptoms of the disease have subsided. As a matter of course, emergencies may arise in any case, contra-indicating its use for a short period, but in the main I wish to impress the importance of a long-continued use of the drug after the patient is seemingly well. A strict uniform observance of this point will prevent many relapses and strengthen the doctor's faith in the ultimate curability of consumption.

Creosote prevents fermentation in the alimentary tract, at the same time it stimulates a better flow of digestive fluids, and allows a disabled organ the time, which it lacked in vigor, to accomplish a physiologic process. Large doses of creosote stimulates respiration, increases oxidation, makes more red blood, gives better nutrition to the tissues of the body and renders a soil less desirable for germ life.

Creosote is largely eliminated by the lungs and kidneys, and, from this very fact, we recognize in this drug a valuable remedy in tuberculosis of these organs. Large doses of creosote, with rest and diet, in tubercular nephritis offers a rational plan of treatment, which is unexcelled. In these large doses I have yet to observe a single instance of renal disturbance, notwithstanding the warning uniformly thrown out by authors.

Creosote has the power of controlling tubercular fever in the incipient or congested stage, as well as in the suppurative stage. By the large doses in the incipient stage the inflammatory area is limited and circumscribed. In the suppurative stage it is not only limited by the large doses, preventing further tissue complications, but creosote thrown down into bronchial tubes and cavities destroys the pus germs, which causes the septic fever.

A married female, 28 years of age, having been located in a good climate eighteen months, with a shot of an attenuated tuberculin every two or three days, presented herself at my office with a temperature chart of the last six months of her illness; the temperature at 5 p. m. had rarely been below 101 and most frequently ranged to 104. She had lost much flesh from tissue metamorphosis and tubercular sepsis. The tuberculin was stopped and the patient was placed upon a strict diet of scraped beef, cream and eggs, with 90 minims of creosote three times daily and with 25 to 30 minims of hydrocarbon oil forced down the bronchial tubes into the lungs daily. A drop in the temperature was noticed the first afternoon following the treatment; at the expiration of twelve days' treatment the afternoon temperature had dropped to 99. She has now been under treatment for ten weeks, with somewhat increased amount of creosote, and at no time since the twelfth day has her temperature been above 99. The cough and expectoration, with all constitutional symptoms, are greatly improved and she has gained sixteen pounds in flesh. It has not been my pleasure to observe in very many cases such prompt and decided lowering of temperature, yet all cases amenable to treatment will show a perceptible reduction of temperature almost from the start with a cessation of loss of weight.

Creosote is not the only drug that is of value, but it

plays a part and exerts an influence in tuberculosis that no other drug does; its influence over this dreaded disease is well-nigh that of a specific, if administered in the incipient stage, other things being equal, viz., climate, diet, and rest of mind and body.

With large doses of creosote by the stomach, and locally in a hydrocarbon oil, it is beautiful to watch the appetite and digestion improve, the heart's action coming down, night sweats ceasing, cough and expectoration decreasing, with a return of vigor, strength and general good spirits born of hope, and a consciousness of decided substantial improvement; happiness, obedience and gratitude come hand in hand with the improvement.

#### DEDUCTIONS.

1. Selection of a creosote made by the double distillation of tar from beechwood is essential.
2. Large doses continued indefinitely do not irritate the stomach, but improve digestion.
3. Large doses are appropriated by the system as shown by clinical observations.
4. The drug in large doses is indicated in all stages of the disease.
5. For permanent results the drug in large doses should be continued for months after the absence of all physical signs or constitutional disturbance.
6. Creosote in large, continued doses is not only the most rational treatment, but gives the best clinical results of any one agent familiar to clinicians.

#### DISCUSSION IN SYMPOSIUM ON TUBERCULOSIS.

DR. DE LANCEY ROCHESTER, Buffalo.—The speaker had sent several cases to Colorado last winter and recalled one case of a man, who weighed only 168 pounds, suffering with tuberculosis, and who, after remaining in Colorado six months, now weighs 208 pounds. Every case that he had sent had improved in the climate of Colorado. He felt that he could add nothing to what Dr. Sally had said, except to emphasize his remarks upon the value of altitude in the treatment of pulmonary tuberculosis.

He approved of creosote. In the city of Buffalo the climate is not a very good one for consumptives, but he recalled five cases, two men and three women, living in tenements, under bad hygienic conditions, which he had cured with creosote in very large doses. He commenced with small doses and ran it up to 4 c.c. at a dose, three or four times a day. The value of this treatment can not be denied. He had found that he gets much better results from plain beechwood creosote than from guaiacol or any of the other drugs which have been used as substitutes for creosote. The best vehicle for administration is weak mucilage water. He had never had any difficulty with his patients about taking the drug. He instructed his patients to buy their gum acacia and make their fresh mucilage solution at the time of taking the dose. He had never observed any ill effects from these large doses of creosote upon any of the organs of the body. He would also emphasize the remarks of Dr. Bridge about keeping the lung at rest. Much harm has been done by pulmonary gymnastics during the active stage of the disease. The theory is wrong and he had obtained better results by keeping the lung at rest. After the patient has recovered, and has been without fever and other symptoms for a month, and all signs of the active process have disappeared and the physical signs are simply those of sclerosis, then we can begin with the hope of benefit the gymnastics to prevent contraction of the lung. He did not think that they should be entirely given up, but that they should not be resorted to until the active stage of the disease has passed away.

DR. SHERMAN G. BONNEY, Denver, said that with reference to the matter of hemorrhage in relation to the altitude treatment, it had been his observation that only one case out of every four with a history of hemorrhage before arrival in Denver at an altitude of 5000 feet might be expected to have a recurrence. This observation was based upon a very large number of cases. He had read recently a paper on this subject, before the Climatological Association, which contained his statistics and he would not repeat them, but he might state that the

majority of cases which had bleeding at an altitude, were cases which had a hemorrhage shortly before leaving their homes, or just before arrival. He would also say that one case out of every four who had a hemorrhage shortly before arrival might expect to have one after arrival, and in a large proportion they will have it within a week or two after coming. The deduction from these observations should not be that such cases are not to have the benefit of removal to an altitude, or that they ascend by easy stages, but that they should wait for one or two weeks after having a hemorrhage, at the lower level, before undertaking the fatigue involved in going to an altitude. He did not think that they should stay away altogether unless there were other reasons than the hemorrhage, to deprive them of the benefits of climate. In many of the cases in which the hemorrhages were severe at an altitude, he had found that they were those in whom unfavorable manifestations might be expected in any locality, and which should never have started. While he was a believer in high altitude treatment of consumption, which is a broad subject, too extensive for discussion now, he realized that no one climate is the best adapted to suit every case. Some will do better at a little lower altitude. For several years in Colorado he had had experience with a number of cases which had been sent away from home without any discrimination whatever; cases of emphysema, of kidney disease, of extensive fibrosis; cases of chronic bronchitis of a dry type associated frequently with asthma, and aggravated forms of heart trouble. The cases just referred to frequently do better at a low level, in parts of California, for instance, than at a high one. He did not attempt to differentiate these patients according to all their clinical appearances, but always with reference to the individual, and the power which his heart possesses. While an extreme altitude is not adapted to all classes of cases, he thought that a great majority of consumptives do better at moderate altitude like 5000 feet than in any other locality.

He thinks creosote valuable, though not adapted to all cases. If given indiscriminately, it is capable of doing much harm. He deprecated the sentiment expressed by many patients who come to Colorado, that they will not take creosote. It is a popular fad at the present day that patients should say what they should take and what they should not take. He believed that creosote should be given in small doses, preferably in capsules. He is usually guided in its administration by the character of the expectoration and by its quantity. In the cases with very purulent expectoration, it is capable of doing very much good. In cases of dry bronchitis, with scanty expectoration, it is harmful. In some cases it may do good by its influence on the digestion, by diminishing fermentation and increasing the appetite. He had been much interested in the several communications by Dr. Bridge with reference to keeping the tuberculous lung at rest. He felt constrained to emphasize the fact, however, that it was far less important to keep the tuberculous lung at rest than to keep the tuberculous individual at rest. A great many patients who come to Colorado, with advanced trouble in the lung—in 71 per cent. the disease has been progressing for eighteen months before arrival—arrived at the stage of the disease of the lung where strapping is inapplicable. In some cases there is often a pleural effusion, and the patients do very well with it. He questioned if it was beneficial to aspirate in these cases; he had seen cases do poorly after aspiration and he had come to the conclusion that a moderate effusion should not be interfered with. Where the disease is active and confined to one lung, the speaker approved of the method of putting the lung at rest, but if there is trouble in both lungs it would do harm. With reference to the use of nitrogen injections into the pleural cavity, where the disease is strictly limited to one side, they may be useful, but the observations which have been made are to a large extent fallacious. It has been the experience of observers that while there is apparent improvement in the symptoms—the cough and the expectoration—upon examination of the lung six months later, it will show very little change in its physical condition. He was not certain that we do not lay ourselves open to the charge of doing harm by indiscriminate strapping,

in a certain class of cases. Damage may result after the straps have been worn for five or six weeks, if we allow the patient to take them off suddenly. In one case, that of a lady who had gone through an attack of influenza with the straps on her chest, the latter were removed one evening with the intention of renewing them the next morning. During the night, she had a severe attack of coughing and developed a pneumothorax. He now observes the precautions of removing the straps gradually with an interval of a day or two between each, so as to gradually withdraw the support from the chest, instead of taking away the straps all at one time.

Dr. C. L. MINOR, Asheville, N. C., criticized the remarks of Dr. Bridge on the ground that in rejecting pulmonary gymnastics Dr. Bridge did not differentiate between incipient and advanced cases. From his paper Dr. Bridge was evidently thinking of advanced cases, which all realize are not suited to gymnastics. If pulmonary gymnastics were to be of value they must be restricted to incipient or not very active cases; to use them in advanced ones might favor the more rapid dissemination of the trouble. Dr. Minor would take issue with Dr. Bridge on his general statement that the tubercular lung should not be exercised. This term, tubercular lung, covers too many conditions to be used without closer specifications, since it applies equally well to the lung with the least possible tubercular infiltration and to that which is totally disorganized. The opponents of gymnastics have always claimed that if we rest the tubercular joint it is equally necessary to rest the tubercular lung, but that a parallel can be drawn from joint to lung is not evident. It is rational to assume that deep breathing in an actively involved lung may do harm, and in such cases as show moist râles or more than a very few dry ones gymnastics are contra-indicated. It is, however, equally rational to assume that since the thorax in the recovering consumptive increases in size and contracted parts of the chest wall re-expanded we can not be far wrong in assisting Nature in her efforts in this direction in suitable cases. The speaker had now for a number of years used pulmonary gymnastics with undeniable benefit both in his own case and in those of many patients, had kept careful lead tape cyrtometer tracings of the chest shape before and after treatment, and could say that, with few exceptions, the thorax of a recovering tuberculous case always increased in size and that when that increase was assisted by gymnastics the patients did not suffer by it but did better and felt better, and that the falling temperature and improving signs showed that the harm Dr. Bridge feared was chimerical. Yearly he saw cases, but not many, where he had to discontinue these exercises for cause, but had yet to see any case which had suffered more than very temporarily from them. He believed that its chief effect was to combat and remove the peripheral atelectasis which in these cases offered such a good ground for the process to spread in.

Turning to Dr. Bridge's treatment by strapping and immobilizing, he did not believe it wise save during a dry pleurisy or after a hemorrhage. That the straps could effectually immobilize the lung he could not believe; certainly he could contradict the Doctor's statement that the arm muscles did not expand the chest; the pectorales, the shoulders being fixed, are well known to have such an effect and a short observation on one's self or a patient would convince one of it. The beneficial effect on an acute case of a rapid pleural effusion was often seen, but the cases helped were always acute, never chronic.

The statement that climate was a non-essential should be contradicted. It was not as essential as strict hygiene and good diet, but added to these it could cure cases that they alone would fail utterly to rescue. Our climatic resorts could show many people who had experienced this; no one who had lived in such a place could doubt that after hygiene and diet, climate took the next place.

Dr. R. C. MOORE, Omaha, said that the advantages of various climates had been well described, but, in his mind, the chief desideratum was a climate where the patient can stay out of doors the most of his time. In any altitude, if the patient remains in his room, he will die. It is the fresh air that cures the patient whether he is in Colorado, California, or elsewhere.

An objection to sending a patient away from home is that by so doing he is often sent to a place where he has less freedom than in his own house, and is in fact in prison. He is also likely to meet with other unfortunates who are exiled from home and the effect is to depress him. Instead of sending his patients to such places, he tells them to go out on a ranch in his own State of Nebraska. He tells them not to be afraid of the fresh air, and not to sleep indoors. It is the constant breathing of vitiated air loaded with disease germs that causes pulmonary tuberculosis and the remedy is to breathe fresh air.

As regards the medical treatment, he had heard many remedies highly praised in this disease, but his experience was that any disease for which there were so many sovereign remedies, was incurable. The less stuff from the drug stores that you put into the stomachs of these patients, the better they are off. He is accustomed to give his patients some strychnia tablets (gr. 1/60), and gradually increase the dose to gr. 1/12, three times a day. This is about the extent of the drug treatment that is used in these cases, and he finds that his patients get on better and live longer than when he used to dose them with all the different drugs that were recommended.

DR. S. E. SOLLY, Colorado Springs—In regard to the statement by Dr. Burroughs that altitude is injurious because expansion of the chest is injurious to the lungs, he would say that while the diseased part of the lung should be kept quiet, the other part of the lung should be expanded and thus allow the diseased part to be at rest. This very thing is brought about by altitude; the healthy portions of the lung were so expanded by the rarefied air that they compressed the diseased portions, keeping them quiescent as in a spint. As regards exercise, he advised at first a period of absolute rest, then massage, Swedish movements, light gymnastics, waltzing, horse-back riding and golf playing. From repose to active exercise must be a path on an inclined plane. He had not had occasion to use injections of nitrogen gas into the chest. He had, however, often seen relief follow a pleural effusion, in which case he would avoid aspirating as long as the patient was doing well. He was opposed to the use of straps to keep the chest at rest. Strapping the chest interfered with the activity of the surrounding healthy lung, which required to be in its highest efficiency for the direct benefit to the tubercular area, as has been spoken of, and also for the indirect benefit to the aëration of the blood. As to what Dr. Burroughs had said about the innocuousness of the pus in the bronchial tubes, it is probably true, as long as it remains in them, but the danger is in its being carried to other parts of the lung. While in the bronchial tubes it perhaps is only harmful in interfering with the air entering the air cells. The speaker was glad to notice that Dr. Bridge was evolving from the seashore, and beginning to remove his consumptive patients from the low damp air to the high and dry atmospheres of the mountains.

DR. NORMAN BRIDGE said that he had observed that not only Dr. Solly but other advocates of high altitudes are apt to apply the name of "stimulating," or "too stimulating" to the climate when explaining why certain cases get worse. For there are certain cases which do get worse, and it is then said that the climate was too stimulating for them. He wished that they would try to find out what this character of the climate really is, or else not use the word. With regard to the value of creosote, he had used it to a great extent and had come to the conclusion that some writers were about right in declaring that no condition of tuberculosis of the lungs is influenced in any way by any amount of creosote taken into the body. The advocates of this treatment have referred to cases which have recovered who had taken large doses of creosote. The speaker could point to a large number of cases that had recovered under precisely similar conditions without taking any creosote whatever; that in a very large number of cases, examined under similar conditions, recovery has followed the use of other agents. Hence, from these cases we can draw no conclusions of scientific value. As to the statement of his friend that he had seen good results from pulmonary gymnastics—

DR. MINOR—Not in active processes.

DR. BRIDGE—He draws the wrong conclusions as to the progress of the tubercular condition in the lung, which may have lesions in all stages.

DR. MINOR explained that he was guided by the temperature.

DR. BRIDGE—There are cases of dry fibroid phthisis which go on to destruction of the lung and death without any particular rise of temperature whatever. The thermometer is not an infallible guide. Dr. Bonney spoke about removing the straps gradually, but the speaker had never seen any bad effect from doing it, and thought the risk was exaggerated. In his remarks about the local treatment of the tubercular lung, he had no intention of minimizing the importance of putting the patient at rest. As regards the effects of the stimulating treatment, Dr. Solly had relieved the speaker's conscience and he had no need to discuss it. The gentleman from Nebraska had emphasized the most important point in the treatment, and without agreeing with everything he had said, the speaker thought that the remarks had embodied a great deal of good sense.

DR. C. S. N. HALLBERG, Chicago—Dr. Burroughs had laid much stress upon the necessity of purity of creosote, and upon the value of the tests which he relied upon. The speaker was compelled to say that creosote is not made by any such simple method as the reader of the paper had described, nor are the tests that he had given to be relied upon. The speaker thought that in prescribing creosote, physicians should pay more attention to the character of the preparation, or form of creosote they use. Creosote is one of the most insoluble remedies. It dissolves with difficulty in water, requiring not less than 150 parts. It is fortunate that it is so, otherwise we should hear of some bad results, as the large doses would seriously impair the digestion. Creosote is broken up by the alkaline liquids of the intestine, into guaiacol and creosol, thus forming more soluble antiseptic compounds. The speaker thought that the best method of administration of creosote is in the form of a pill (5 eg.) made with a soapy excipient, which passes unchanged through the stomach, and upon arriving in the intestine, slowly disintegrates. Dr. Hare, a few years ago, advised the administration of creosote water, a saturated solution (1 in 150), as being the best form in which to administer it. The method of administering creosote undiluted in capsules containing larger doses, 1 c.c. or more, is similar to that employed by railroad men for preserving the wooden ties from decomposition, in which the wood is creosotized.

The Doctor from Nebraska had spoken of the administration of strychnin in the form of tablets. The speaker called attention to the sparing solubility of the tablets in the alkaline intestinal tract. If a number accumulate in the intestine they may through changes in reaction dissolve at once and have serious results.

DR. A. C. KLEBS, Chicago, agreed with Dr. Solly's remarks upon the distinction to be made in the selection of cases for altitude treatment based upon the patient's social and financial condition. It often happens that patients are sent to an altitude as to an Eldorado; they are sent en masse to some celebrated health resort, and are in many instances just able to gather together a few dollars to take them there and with absolutely nothing to live on when they get there. Certainly, such warning as Dr. Solly had given was most valuable, and physicians should most carefully consider the social condition of the patients when advising the altitude treatment. Dr. Burroughs had made some unsupported statements; the statistics given were not satisfactory; they lacked in exactness and did not afford any explanation, and besides were based upon too few cases to be of any value. The administration of remedies by inhalation of sprays does not affect the tubercular lesions, and it has been abandoned by good authorities. Dr. Burroughs made the statement that the treatment of tuberculosis by creosote is a rational treatment; but the facts he produced do not seem to substantiate such a statement. Dr. Bridge's paper on the treatment of a tubercular lung was of the utmost interest, and the speaker was very glad to hear him emphasize two points: the prevention of useless cough, and the importance of rest to the lung itself. The former has

not had sufficient attention given to it. Patients should be instructed that a certain amount of cough and expectoration are necessary, particularly in the morning after a night's rest; but they can be taught to control excessive coughing by attention to certain points; they can learn to control the cough by will. They have to cough in the morning; but if they can refrain from responding to the slightest irritation and wait until after breakfast, the expectoration can be accomplished with much less exertion. Everyone should read the classical essay by Dr. Detweiler on the restraining of unnecessary cough. The gentleman from Nebraska has struck the key-note, which had been already mentioned in the speaker's paper, that true science is only systematized common sense. If he would systematize his common sense he would be very near the truth. His reference to the fresh air wherever found and its influence in effecting cure was very good. Without detracting from the effects of climate and altitude, it is the open air as such that is one of the chief factors. The climates that permit the greatest opportunities for living in the open air are the best climates for the treatment of pulmonary tuberculosis, but this in no way alone constitutes everything; every feature in the patient's life demands attention and careful regulation under the supervision of a competent physician.

### TREATMENT OF ACROMEGALY WITH PITUITARY BODIES.\*

SYDNEY KUH, M.D.

Professor of Diseases of the Nervous System, Chicago Post-Graduate Medical School; Assistant Clinical Professor of Nervous Diseases, Rush Medical College; Attending Neurologist, Michael Reese Hospital; Fellow, Chicago Academy of Medicine, Etc.

CHICAGO.

Changes of some kind have been found in the pituitary body in all cases of acromegaly, in which there could be no doubt about the diagnosis, and in which a careful macroscopic and microscopic examination of the hypophysis was made. This is conceded by almost all writers who have contributed to our knowledge of the subject. Some, however, claim that the enlargement of the hypophysis is but one of the effects of the malady, something similar to the enlargement of the spleen, for instance, which has been found so often in acromegaly. They forget that in many cases we find not a simple hypertrophy or hyperplasia of the gland, but a malignant growth which does not in any way resemble the simply hypertrophic tissues found in other parts of the body. They also forget the fact—impossible of explanation if their view were correct—that in very nearly all acute cases of acromegaly a sarcoma has been found. I have said that in all cases of acromegaly the hypophysis was diseased. Both Hinsdale and Sternberg, who have collected the reports of 57 and 47 autopsies respectively, claim such changes for all of these cases. The literature, however, contains a few instances of apparent exception to this rule, such as the ones reported by Arnold and Sarbo. In the first of these I witnessed the autopsy myself, and I know that at that time Arnold did not make a positive diagnosis, and I do not believe that he has done so since then. Sarbo's case is also one of very uncertain diagnosis. Then, there is one instance quoted in literature in which the hypophysis is not even mentioned; that a thorough examination of the gland was made seems extremely doubtful. Labadie-Lagrave and Deguy report another case of acromegaly, without changes in the pituitary body, but they made no microscopic examination of any part of the body. It seems, then, that

Sternberg and Hinsdale, Grasset and Rauzier and others were justified in pronouncing lesions of the hypophysis a constant finding in acromegaly. There is, as far as I am aware, but one case of this disease known to have occurred in an animal, the one reported by Cunningham, and he found the hypophysis of his dog enlarged.

Several theories have been propounded which are to explain just how the disease of the gland causes this peculiar form of giantism, but the material at hand forms an insufficient basis for a positive answer to this question. Joffroy thinks that when the pituitary body is diseased and over-active, acromegaly results, excepting when the patient is very young, when giantism is supposed to be the consequence; that if the gland be destroyed, atrophy and cachexia result, a condition similar to cachexia strumipriva. Hansemann, too, believes that an increased activity of the gland is the pathogenetic factor. Since we know of one case of acromegaly in which the pituitary body was entirely wanting, this explanation can not be correct. I should not, however, feel justified in considering a single case a sufficient basis for a theory; otherwise the only possible conclusion would be, that a decreased secretion is the causative factor.

A number of facts seems to indicate that the hypophysis in some way exerts an influence upon the growth of the body. These I wish to refer to briefly. In a paper on cerebral localization, read by me at a joint meeting of the Chicago Medical and Chicago Neurological societies last year, I spoke of one of my cases in which a psammoma of the pituitary body was found postmortem, and which intra-vitam had shown not the symptoms of acromegaly or giantism, but those of stunted growth. The patient, at the time of his death, his 18th year, was about as tall as the average boy of 14, and his parents stated that his physical development had ceased at that age. His genitals were still infantile. The only cause for the dwarfism that could be found was the tumor of the hypophysis. The thyroid gland was not examined at the autopsy, but seemed of normal size during life. A search in literature for similar cases yielded the following results: Levy, in his thesis, reports the case of a woman, 33 years of age, who died of lymphosarcoma of the hypophysis. The record of the postmortem findings contains the words: "Infantiler Zustand der Genitalien." Another similar case is that of Pechkranz, a tumor of the hypophysis in a boy of 15. The patient is of average size, but his sexual organs are undeveloped, "like those of a boy of 5." The case of Uthoff is somewhat more complicated. He examined a girl, 14 years old, who had developed normally up to the age of 9. At that time she is supposed to have had pneumonia, and since then physical development had ceased entirely, while intellectually the patient appeared normal. The case is complicated by the fact that the thyroid seemed abnormally small, but there were no signs of myxedema; the skin was thin, rather atrophic. Uthoff found temporal hemianopsia with atrophy of the optic nerves, and hemianoptic reaction of the pupils. He is of the opinion that the hypophysis must have been diseased. His theory is that at the age of 9 degeneration and atrophy of the thyroid began, which caused stunted growth and secondarily enlargement, and degeneration of the hypophysis. Benda, in his paper on the normal and pathological histology of the hypophysis, mentions that both he and Hutchinson found changes in the hypophysis of dwarfs. And this leads me to another group of facts which seem to support the view that the pituitary body in some way influences the development of the body, that is, the re-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon, and N. S. Davis, Jr.

tionship which evidently exists between the function of this gland and the thyroid. That the latter has some such function seems established beyond all reasonable doubt by our experience in cases of cretinism. It is well known that extirpation of the thyroid gland in animals is followed by hypertrophy of the hypophysis, more particularly of its anterior portion; both glands are known to contain iodine; both have a similar histological structure; both secrete colloidal material; in myxedema the pituitary body is almost always diseased; the same is true of the thyroid gland in acromegaly. Revilliod furthermore has noted changes in the extremities in exophthalmic goiter, which, in his opinion, represented the exact reverse of what is generally seen in acromegaly. Finally, it may be well to call attention to the fact that exophthalmic goiter and myxedema—both of them rare diseases—have been found associated with acromegaly in so large a number of cases that the appearance of these diseases in the same individual seems rather beyond the probability of a mere coincidence.

Those who do not believe that lesions of the pituitary body are the cause of acromegaly make much of it that occasionally the hypophysis has been found diseased in those who were not acromegalic. Would they have us believe that because they are goiters without myxedema or Graves' disease, the thyroid has no influence upon the development of these maladies?

The considerations just given seem to offer a sufficient justification for experiments with the feeding of powdered pituitary bodies in cases of acromegaly. The results of a series of such experiments in three cases were the following:

CASE 1.—D. P., 20 years old, tailor, Jewish. His parents are alive and healthy; of his nine brothers and sisters, only two are living, but the rest seem to have died from diphtheria. There is no history of any nervous disease or trouble similar to that of the patient in the family. His three children are also healthy. He himself has had typhoid fever some fifteen to eighteen years ago, and a fall ten to eleven years ago; since then he complains of pain in left side. He has used alcohol in moderation, never smoked. It was not possible to ascertain definitely how long he has been ill; he thinks that it is about five or six years since he first noticed an enlargement of peripheral parts. For four or five years he has been depressed mentally at times. His head has troubled him a good deal for three to four years. The pains are described as sticking, are not confined to any one part of the skull; with them he has had considerable dizziness, said to be particularly intense when he looks to the left. At times there has been pain similar in character to the headache in the left eye; occasionally, some tinnitus. During the last two years he has gradually become weaker. His voice has been changed for four to five years. Frequent micturition, but as far as patient knows no change in appearance of urine. Constipation. Of late, gradual decrease of sexual power.

Patient measures 5 feet, 9 inches in height; is well built; somewhat anemic. General state of nutrition seems fair. Memory and intellect corresponding to his social condition. Slight mental depression. His skull is very large, square, measures 25 inches in circumference. The temporal ridges of the frontal bone and the zygomatic bones are very prominent. The skin of the face seems thickened; the pores are distinctly enlarged. Lips also very thick. Hair appears rather coarse. Eyes: motility normal; no exophthalmos; pupils normal in every way. At the time of the first examination the fundus and vision were normal; since then, however, the patient has developed both optic atrophy and a bilateral diabetic cataract (Dr. Hale), and his vision has become very poor.

The nose is abnormally broad and generally thickened; sense of smell impaired on both sides. Ears are somewhat deformed (congenital), large; hearing good.

The lower jaw is very large, square; the palate presents an unusually high arch, and a very pronounced torus palatinus. The tongue measures  $2\frac{1}{4}$  inches in width, is rather thin, shows a coarse muscular tremor. The reflex from the soft palate is present, also that from the lower maxilla. Speech thick, evidently on account of the large tongue. The voice is deep and hoarse. Teeth not altered. Patient claims that there is an increased secretion of saliva (difficulty in swallowing on account of large tongue?). Thyroid gland not to be found. Some dullness to percussion over upper part of sternum. Abdominal organs normal. Genitals of average size, excepting testes, which are rather small. Spinal column straight. No enlarged glands. Neck is broad and thick; in lower occipital region a heavy fold of thickened skin. The patient's entire thorax is very large, the sternum broad and thick; the clavicles and ribs seem affected in the same way. It is hardly necessary to describe in detail the changes in the upper and lower extremities; they are those characteristic of acromegaly. The muscles of the forearm seem rather hypertrophic. The patient's gait is that of a man who is very tired. A few measurements will serve to give an idea of the size of the parts affected. The greatest width of the hand is  $8\frac{1}{4}$  inches; the circumference of the index finger  $3\frac{1}{2}$  inches; that of the middle finger about  $3\frac{1}{2}$ , that of the thumb  $3\frac{3}{4}$ . Length of hand from wrist to tip of middle finger  $7\frac{1}{8}$  inches. The thorax measures  $46\frac{1}{2}$  inches in circumference in its upper end, and 43 in its lower parts. The foot is  $4\frac{1}{4}$  inches broad,  $11\frac{1}{8}$  inches long. The clavicles measure  $7\frac{1}{4}$  inches in length.

Sensibility appears to be normal all over the body. The cutaneous reflexes were of the usual intensity; the deep reflexes diminished or absent. The patient's feet were cold and damp. General hyperhidrosis. No trophic disturbances in nails.

The course of the disease in this case seemed to be slowly progressive. I have already mentioned the fact that atrophy of the optic nerve was found later on, and a cataract due to the appearance of sugar in rather large quantities in the urine. The patient seemed to lose in strength, and became more and more emaciated. For a short time thyroid feeding seemed to give some relief. The appetite became better; the bowels more regular; headache and dizziness decreased, and the patient felt some stronger. But it soon lost its effect. For the last ten weeks the patient has been taking powdered pituitary bodies, as he stated, without any change for the better. When, however, this medication was stopped for a week, he came and begged that he be given the same powders, for since he had stopped them his headache had become much more intense. It seems to me as though, during the last few weeks, the mental depression had been much less marked.

Since this was written we have repeatedly withdrawn the pituitary bodies for a short time, without any decided change in the patient's condition, excepting, perhaps, an increase in the mental depression.

CASE 2.—Patient, C. P., 30 years of age, Swedish, unmarried, cook. Examined April 24, 1899.

Family history: The patient's father died of old age; her mother succumbed to an attack of pneumonia; four sisters and one brother are well. No similar case has ever occurred in the family.

The patient's past history reveals nothing that could in any way be considered an etiologic factor; no indications of syphilis; no alcoholism; no mental or somatic trauma; no infectious diseases; no nervous symptoms of any kind.

The present trouble seems to have begun very gradually within the last year or two, but it is not more than one year since the symptoms became more marked. Within that time the patient has noticed a gradual enlargement of hands and feet, which compelled her to change the size of shoes and gloves, so that now she wears both of them two sizes larger than a year ago. She found greater difficulty in doing finer work, her hands had become "clumsy." Her voice has become

more and more hoarse, so that the girl could no longer sing, formerly a favorite pastime with her. Then she also began to have trouble with her finger-nails; they became brittle and would break frequently while she was at work; the skin surrounding them would become thickened and inflamed, and the nails would drop off, but would very soon be replaced by new ones. She has suffered from headache almost continually since ill; at times this pain becomes terrific, and is then associated with vomiting. There has been an increasing weakness since last winter, and off and on an itching sensation all over the body. The appetite has always been fair, the bowels constipated. In spite of being ill, the patient claims to have gained some in weight. Just how much she does not know. Menstruation has always been normal. When I saw the patient for the first time, she was suffering from one of her attacks of very violent headache, and with it she had typical, projectile vomiting. Only after repeated large doses of morphin did she obtain some relief from the pain. She felt unable to continue her work on account of general weakness, and was sent to the Michael Reese Hospital for treatment.

Examination on April 26, 1899: The patient is not unusually tall, has a good panniculus adiposus. Slight degree of anemia. On the skull the changes are but slight. The frontal region appears somewhat more prominent than is normal; the lower jaw is large and projects some. Tongue and lips are not thickened, nor are the ears enlarged. The thorax is large, though perhaps not pathological. Thyroid gland of average size. No enlarged lymphatic glands. The changes on the hands and feet are quite characteristic. There is a general enlargement of these parts, no deformity of the same. Both tibiae are also of uncommon size and thickness. The hair appears to be normal. No hyperidrosis. The finger-nails are all more or less diseased. They are thickened, abnormally brittle, marked by distinct transverse furrows; in some instances the ragged ends are discolored, black. Where the old nail is about to be shed, a new one may be seen under the remnants of the old one.

The heart and lungs show no evidence of disease. There is no polyuria, but examination of the urine shows the presence of a trace of albumin, and a few hyaline and granular casts. No sugar.

There was some horizontal nystagmus, and Dr. A. B. Hale, who kindly examined the eyes for me, found beginning atrophy of the optic nerves, with normal retina. The pupils reacted both to light and to accommodation, and there was no paralysis of extrinsic ocular muscles. I am indebted to Dr. Pierce for an examination of the larynx, which showed the following changes: "Interarytenoid folds thickened; on true vocal cords nodular swelling; false cords also thickened; motility normal; slight swelling below the commissure."

Both knee-jerks were very brisk: ankle clonus could be obtained on both sides. Mentally, the patient appeared perfectly normal. There was no loss of memory, no somnolence, no mental depression.

The patient remained in the hospital from April 26 to June 3, 1899. During that time the temperature was always normal, excepting one rise to 99. The pulse rate ranged from 60 to 100; twice it was 60 and twice 64.

We first gave 15 drops of saturated solution of potassium iodid, t.i.d., and codein, gr. 1/3, for pain, when needed. On May 7, we began to administer powdered pituitary bodies. The dose was 5 grains, three times daily. Up to May 8 it had been necessary to give codein five times. After that date the patient had no further attack of headache that called for an anodyne.

She improved steadily, as far as the subjective signs were concerned, and during the one and one-half years that she was under observation had but one attack of headache, and that after she had been without the pituitary bodies for several days. She was then ordered to continue the gland, and has been free from headache since then. She had regained her strength sufficiently to take up her work again shortly after she left the hospital, and until August of last year felt well, with excep-

tion of the attack just mentioned. At that time, however, she began to suffer from violent cramps in the calves of the legs, which came on very frequently during the night, causing insomnia. At the same time her mental condition changed, she became depressed and very emotional, was convinced that she would become a cripple, etc. In September she returned to her old home. As far as the objective signs of the disease are concerned, I could not discover any change either for better or for worse during the last one and a half years.

CASE 3.—M. H., 58 years of age, retired merchant. Jewish. Patient was first examined Jan. 16, 1900.

His mother was a nervous woman, died at age of 65 "from asthma." The father is now 80 years old, suffers from stomach trouble. Of the brothers, one is said to have died of tuberculosis, one of heart trouble, four are living, all of them asthmatic. I had occasion to examine a photograph of all the members of the family; none of them showed any signs either of acromegaly or of giantism. Of the patient's children, one died of inflammatory rheumatism. The rest are living and, excepting for nervousness, well.

Patient has suffered from rheumatism off and on. He has always worked very hard, and has been exposed to the inclemencies of the weather a good deal. He has had a good deal of trouble and worry during the last few years. He has never used alcohol to excess, but has smoked a great deal. He has not been nervous. For years he has had frequent attacks of asthma. During the last six to seven years he has had more or less headache. His present illness, he thinks, dates back about three or four years, and began with attacks of vertigo, during which objects seemed to revolve around the patient. For two to three years his bowels have been constipated, and he has had a good deal of headache, always in left frontal region, dull. His hands feel stiff and weak. Frequent pain in lumbar region. He has not noticed the enlargement of the extremities, but during the last few months others have frequently called his attention to these changes; his head, he claims, was always very large. At times during the last two years he has had trouble in closing the left eye. His vision is good. For the last year he has noticed attacks of palpitation. The urine was examined one year ago, and found normal. He is troubled considerably by polydipsia. Sleeps good. At times some tinnitus aurium. Of late he has not been able to eat solids any more, because the lower set of teeth projected so far beyond the upper ones that he was unable to masticate. During the last two years he has perspired very freely. He was examined on a rather cool day, but his underclothing was fairly soaked with perspiration. The patient is about 5 feet, 8 inches tall, weighs 193 pounds; is well nourished. The skin of the face seems thickened, the pores enlarged. His skull measures  $24\frac{1}{4}$  inches in circumference. To describe it would mean merely to repeat what I have said about the cranium of Case 1. His ears are large, somewhat thick; his nose broad, large and thick. The color of his eyes is brown, with numerous black spots on iris; the motility is normal, excepting for an occasional trace of horizontal nystagmus. Pupils react normally. No changes in fundus. Senses of taste, smell and hearing not affected. The hard palate is very high, arched, the tongue broad and thick. His voice is deep, hoarse. The respiration is rapid and labored. Thyroid gland of about normal size. Heart: Mitral insufficiency; arteriosclerosis; pulse, 76. Emphysema of lungs. Spleen not enlarged. Marked gibbus and curvature of the spinal column to the right. Glands not enlarged. Both the cutaneous and deep reflexes are normal. His hands, as well as his feet, show the changes characteristic for acromegaly. The long bones in the extremities seem somewhat thickened, too. The clavicles and ribs are distinctly enlarged, particularly broader than normal.

Examination of urine: Specific gravity, 1025; urea, 2.5 per cent.; no albumin; some hyaline and granular casts.

The patient was put on 5 grains of the powdered pituitary bodies, t.i.d. On Feb. 2, 1900, he reported that he had had very little headache since he took the powders; felt "less weak-

ness in the bones," had but little vertigo and is troubled less by hyperidrosis.

April 27, 1900: Patient has been in California for last two months. Very much less headache, no vertigo at all. Feels stronger. No pain in back; no more hyperidrosis. Appetite good.

In this condition the patient remained up to December, 1900. He "felt better than he had been for years." At the time just mentioned he had an attack of asthma, which was followed by edema of the ankles, and the appearance of albumin in the urine; his pulse became very rapid, irregular and weak. Under digitalis and strophanthus he first improved, but became worse again very suddenly on the morning of December 31, and died on the same day. It does not seem probable to me that his acromegaly had anything to do with his death; the exitus seemed due to the cardiac and renal disease.

The result of the treatment with pituitary bodies, then, in these three cases, was that the first patient derived little, if any, benefit from it, while in the other two cases, for one and a half and one year respectively, the condition of the patients seemed decidedly improved. Headache, dizziness, general weakness, hyperidrosis and vomiting disappeared, while the trophic changes in the nails of our second patient became very much less marked. With her new symptoms appeared, almost as troublesome perhaps as those from which she had been relieved. Still, if we will stop to consider how little other methods of treatment can do in this disease, even the slight improvement obtained seems gratifying. The most important question for us is: Did the feeding with pituitary bodies exert any beneficial influence whatever? This question, for the last two cases, at least, is to be answered in the affirmative. We have not forgotten the possible effect of suggestion, and have tried, as far as possible, to exclude its influence. The fact, too, that in two cases tablets of pituitary bodies seemed to yield less satisfactory results than the powder, although it had been impressed upon them that both contained exactly the same ingredient, seems to me to point rather to a difference in solubility than to a mere imaginary effect. It is hardly reasonable to expect the treatment to cause those symptoms to disappear which are due to organic changes in the tissues, such as the optic atrophy or the enlargement of peripheral parts, but the subjective symptoms were relieved both in two of my own cases and in quite a number of those recorded in literature.

## THE TEACHING OF PRACTICAL DIETETICS IN MEDICAL SCHOOLS.\*

R. O. BEARD, M.D.

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF MINNESOTA,  
MINNEAPOLIS.

In state legislatures within the past two years the medical profession has had to defend itself against the ancient presumption that its practice is essentially based upon the administration of drugs, while other so-called systems of healing have claimed exemption from the operation of medical practice laws upon the plea that their followers do not employ medicinal agents. The contention is an odd one in days when therapeutic nihilism has widely invaded the ranks of the profession of medicine, but it has, together with that nihilistic tendency, a common cause.

Drug dosage is not the dominant rule of practice that it once was, howsoever the reputation of that rule clings persistently to the skirts of the profession. But, while medicinal measures have been finding their proper place in the treatment of disease, other and non-medicinal measures have been rising into recognition and awaiting their assignment to a fit place in the armamentarium of the physician. That these measures have not always been the subjects of medical discovery has unfortunately hindered their ready adoption. The profession has not been invariably hospitable to new truth, while it has clung to ancient and uncouth dogma, at times, with the tenacity of the theologian. It has often had to be shaken out of its indifference to actual progress by popular agitation over some modern fad, which had a reason of partial truth underlying its unreasonable being. The "blue-glass craze" had its meaning in our neglect of the influence of light and color upon animal as well as vegetable nutrition. That "christian science" has been a medical as well as a religious cult, is incident to the failure of our own following to appreciate sufficiently the psychologic element both in the causation and cure of disease. The rise of osteopathy signifies our undervaluation of manipulative measures of treatment. The success of the sanatoria reflects upon our ignorance of practical dietetics.

Medical educators, who have been particularly conscious of the stress which scientific progress has put upon the study of modern medicine, have been especially slow in the adoption of new measures of treatment into the curriculum of the schools. Admirable as this conservatism is, in a day when truth is rapidly leavening a great mass of heterogeneous material and when it is often difficult to distinguish by-products from ultimate

results, yet this is a habit which has sometimes left the schools in the rear rather than in the van of movement. The too-long-delayed teaching of the therapeutics of suggestion and of mechano-therapy in medical courses, are illustrations of this disposition of the teacher to follow rather than to lead.

In no subject, however, has medical need been more insufficiently met by educational supply than in that of practical dietetics. With the clearer definition of a large class of nutritive disorders, dependent upon the non-correlation of digestive, metabolic and eliminative functions, and with the growing recognition of the liability of the alimentary canal to bacterial and parasitic invasion, the study of foods and methods of feeding, in relation alike to the maintenance of health and the treatment of disease, has become one of very great importance. Yet the writer ventures the very strong assertion that there is no subject related to the practice of medicine of which the average physician knows less. This prevailing ignorance is not a matter of neglect upon his part, but of necessity. The medical institutions of learning of the past have taught him nothing. To-day they offer little—in most instances nothing—in the way of practical instruction. Two colleges—the department of medicine of Harvard University and that of the University of Minnesota—provide laboratory courses in this subject. In the latter, and presumably in the former school, these courses are elective. Their election by a great majority of the senior students and the enthusiasm with which the courses are pursued, attest their answer to a recognized need.

Text-books upon dietetics are lamentably few and, still more unfortunately, inferior. They do little more than to meet the serious want of the would-be student with series of dogmatic statements, which justify much of the skepticism of their actual authority felt by practical men. It is not strange that in practice dietetics has been pursued, if pursued at all, in a purely empirical manner.

How can the deficiency be met? What place and what scope should a course of study in practical dietetics in the curricula of the medical schools take? How can it be made most available to undergraduate and post-graduate student alike?

The experience of the department of physiology of the University of Minnesota, in its effort to fulfill this need, may be cited as a practical attempt to find answers to these queries: 1. The course in practical dietetics has been placed in the senior year. It stands thus, where it belongs, among the clinical branches, with which it is in practical association. So placed, it can most readily offer its opportunities to the post-graduate student. 2. It is an elective and one of an increasing number of electives which are provided in the senior year. The congestion of compulsory work, which has not been relieved by the addition of a fourth year of medical study, has developed a growing tendency to a division of the courses into required and optional branches. This tendency is in accord with the similar movement along all educational lines. Not the least merit of cultivating the principle of choice of study is the added interest of the student in a chosen work. The classes which have elected the course in practical dietetics have shown a very gratifying interest in its pursuit. Men have demonstrated a success equal to that of women in the diet laboratory. 3. The course in dietetics is essentially practical. It is conducted under the chair of physiology and it conforms in method of study to the subject of which it forms a part.

\* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee.

Its first concern is to acquaint the student with the content of common foods. In his physiologic studies he has become familiar with foods in metabolic classes, as proteids, carbohydrates, fats and salts. Of the proportions, relations and character of these foodstuffs in meats, breads, vegetables, etc., the student and the practitioner of medicine usually know nothing. It is the business, therefore, of this course to teach him the composition of the common articles of dietary, the dominant or most valuable food qualities of each and the means by which these qualities may be best conserved or elaborated.

With this content learned, he is taught to compare and select the several forms of food, with some reference to their economic value, in order that he may suit his selection to the circumstances of those with whom he has to deal. He learns, too, to estimate foods by their several standards of valuation, with reference to their digestive, nutritive, metabolic and esthetic qualities, inquiring how these qualities compare, conflict or may be made to harmonize with each other. He is taught that harmony between these several values is essential to the highest selection of foods.

At the same time, he undertakes the study of the principles and practice of food preparation. He does not learn merely the art of cooking, or even of hygienic cooking, in the ordinary sense of the word. The laboratory of dietetics is not simply a cooking school. He learns not to build menus, but to assist in building tissues. He is constantly reminded of the uses to which food materials are to be put, of the processes to which they are to be subjected within, as well as without, the body. Food preparation, or the actual cooking of foods, is in fact minimized, in sympathy with the best physiologic teaching. No method of cooking is taught which does not or should not improve the digestive, conserve the nutritive and enhance the metabolic qualities of the food.

In relation to food preparation, he studies the office and limitations of heat as a means of cooking, the best methods of obtaining and utilizing heat for cooking purposes, the most desirable forms of cooking apparatus and utensils, and the several processes by which food may be profitably prepared. Incidentally, he learns the adaptations of different foods to conditions of disease, the modifications of food which the sickroom may demand and the forms of food suited to successive periods of life.

#### COURSE OF STUDY.

Two lessons are devoted to milk. They require a study of the content and percentage composition of human and different animal milks; they discuss methods for the modification of milk for infant uses; they teach the process of its predigestion, and the use of measures for the improvement of its digestibility and for the variation, in many ways, of its flavor. Similarly, eggs, cereals, bread, modifications of bread, meats, fish, soups, vegetables, fruits, plain puddings, cold desserts, beverages and infant foods, are severally studied.

Brief talks are given in connection with the practical lessons, in which the various methods of cooking, the different means of employing them, the selection of foods in market, the serving of foods especially for the sick, the choice of food in diseased conditions, etc., are discussed. The students work in pairs, and each pair is provided with a complete outfit of the most improved cooking utensils and has access to gas stoves and Aladdin ovens for the preparation of foods. Each tests and submits the product of the work to the approval of the staff.

A lady instructor in dietetics, who has been practically trained in the best schools of domestic economy, as well as in the University itself, and also the demonstrator of physiologic chemistry, assist the chair of physiology in the conduct of this course. At the close of the sixteen weeks of study the members of the class are competent to select, prepare and serve, physiologically and, at the same time, artistically any desirable form of food. They can intelligently criticize or direct the cooking of a meal or of any special diet.

It is with the hope that this practical addition to the medical curriculum will commend itself to the intelligence of the profession and, particularly, to the educator in medicine, that this brief notice is called to this initial and still novel attempt in the teaching of practical dietetics.

### THREE CASES OF PARALYSIS OF THE SERRATUS MAGNUS AND THE TRAPEZIUS— ALAR SCAPULA.\*

AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic;  
Physician to the Philadelphia Hospital; Assistant Physician  
to the Philadelphia Orthopedic Hospital and Infirmary for  
Nervous Diseases; Physician to Hospital for Diseases  
of the Lungs at Chestnut Hill.  
PHILADELPHIA.

The scapula affords attachment for many large and powerful muscles that play an important part in the varied movements, not alone of the shoulder but also of the entire upper extremity. Thus, the trapezius aids in elevating the scapula and approximating it to the spine; also in rotating the scapula, causing the acromion to ascend and the lower angle to move outward. The action of the trapezius is supplemented by that of the elevator muscle of the angle of the scapula and of the rhomboids, the latter of which rotate the scapula on its outer angle and cause the lower angle to move inward. The serratus magnus moves the scapula outward, forward and slightly upward. It tends to rotate the scapula on its inner angle and thus to elevate the acromion, but in this it is opposed by the elevator muscle of the angle of the scapula and the rhomboids. It also helps to keep the scapula applied to the chest. The deltoid abducts the humerus to the horizontal and also moves the arm both forward and backward. The supraspinatus aids the deltoid in abducting the arm, moving it forward and rotating it inward. The infraspinatus and teres minor rotate the humerus outward, while the subscapular rotates the humerus inward. The latissimus dorsi lowers the arm when it is raised, displaces it backward, adducts the scapula, depresses the shoulder, inclines the trunk and, acting with its fellow, extends the trunk. The pectoralis major brings the shoulder forward and upward or downward in accordance with the position of the arm. The teres major approximates the humerus and the outer border of the scapula, adducting the former and rotating the latter.

The actions of the several muscles named are, as will be seen, not simple, but complex and associated, so that any deficiency that might result from impairment or loss of the function of any one or more might be in large measure made good by the compensatory action of others. In addition, the muscles under consideration are innervated principally from the brachial plexus or the nerves constituting or originating from it, although

\*Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

some of the muscles receive fibers from the cervical plexus, and the trapezius is supplied by the spinal accessory; so that, while it is not impossible for disorders affecting individual muscles to occur, it is more likely that several will suffer as the result of a single lesion.

Isolated paralysis of the serratus magnus is rare. It is often complicated by paralysis of the deltoid, the supraspinatus, the infraspinatus and especially one or another portion of the trapezius. It is said to suffer often on account of the superficial and long course of its supplying nerve—the long thoracic on the side of the neck and chest. The most common cause is injury to the nerve in its peripheral course, as by a blow, a fall; or pressure, as by a heavy weight upon, or a crush, a punc-

ture to the muscle itself. Instances of hysterical paralysis of the serratus have also been recorded.

Paralysis of the serratus magnus is, by reason of the etiologic factors, more common in men than in women, and, apart from infection and refrigeratory causes, as well as progressive muscular atrophy and dystrophy, occurs principally in adults and is more common on the right side than the left. Occasionally the muscles on both sides are affected in succession. The onset of the paralysis, particularly if of peripheral origin, is often preceded by pain in the supraclavicular fossa, radiating to the ear, the occiput, the scapular region and the arm, and this may persist for a variable period of time.

There has been some difference of opinion as to the position of the scapula when the arm is at rest in the presence of paralysis of the serratus. By some it is thought that the shoulder undergoes no change in position under these circumstances; others, however, have contended that the scapula becomes elevated and its inner border approximated to the vertebral column and

Fig. 1.—Displacement of the right scapula when the patient first came under observation.

ture or a gunshot wound of, the shoulder, involving especially the supraspinous region; or compression by contraction of the scalenus medius muscle, through which the nerve passes. The nerve, further, may be injured in various ways in the axillary cavity. Cold and wet and the influences thought to be contributory to rheumatism may cause serratus-palsy, and inflammation of the long thoracic nerve may develop in the course of infectious diseases, typhoid fever, influenza, diphtheria, rheumatism, erysipelas and the puerperal state. The serratus magnus may suffer, together with other shoulder-muscles, in the presence of progressive muscular atrophy, progressive muscular dystrophy, acute anterior poliomyelitis, less commonly in the presence of cerebral paralysis and least of all in consequence of direct injury

Fig. 2.—Displacement of the right scapula after the patient had been under treatment for two months.

directed obliquely upward and outward from below, while the inferior angle exhibits a wing-like projection backward and the outer border assumes a more nearly horizontal position. More recently it has been maintained that the median border retains its direction parallel with the vertebral column.

Generally the patients are unable to elevate the arm above the horizontal, and when this is attempted the median border of the scapula approaches the vertebral column. If the arm is held horizontally in front the median border and the inferior angle of the scapula are removed from the thorax and the scapula stands off like a wing, an excavation resulting, in which the hand can be introduced. The arm can sometimes be raised above the horizontal by means of a sudden jerk, especially if

the upper part of the body be inclined backward. This movement can be effected also if the inferior angle of the scapula be rotated downward and outward and be pressed against the chest by another person. The patient also has difficulty in performing pushing movements and in crossing the arms in front. Sensory changes are generally wanting, and the electric alterations vary with the nature and the intensity of the underlying cause.

Paralysis of the trapezius may result from exposure to cold and wet, gun-shot and punctured wounds, blows, operations, disease of the vertebral column and the posterior portion of the base of the skull, of the spinal cord and medulla, or inflammation of the accessory nerve from any other cause. It may be a manifestation of syringomyelia or of tubes, or of progressive muscular dystrophy or spinal progressive muscular atrophy. The symptoms vary in accordance with the portion of the muscle affected and the degree of involvement. The trapezius is constituted of three parts: an upper or

does not rise so high as its fellow. The elevator muscle of the shoulder becomes prominent. The arm can be raised above the horizontal, especially if the clavicular portion is but little if at all affected, though not so well as its fellow, nor can the shoulder be drawn backward as well as normally.

The upper portion of the trapezius often escapes and when involved is so after the others. The middle and lower portions are usually involved together, though the latter may suffer before the former. When the upper third is involved moderate elevation of the shoulder is still possible. The affected shoulder is raised in deep inspiration. Paralysis of the middle third gives rise to a rocking movement of the scapula. The acromial extremity is lower than usual, while the inferior angle is higher

Fig. 3 Displacement of the right scapula when the upper extremity was extended horizontally at the side.

clavicular, a middle and an inferior. The first or respiratory portion passes from the occiput to the outer third of the clavicle and draws the head downward and rotates it to the opposite side when the shoulder is fixed. The middle portion passes from the ligamentum nuchæ and the upper three dorsal vertebrae to the acromion and outer half of the spine of the scapula and is the proper elevator of the scapula. The inferior portion passes from the fourth dorsal vertebra and goes below to the inner half of the spine of the scapula and brings the median border of the scapula toward the vertebral column.

If the entire muscle is paralyzed the shoulder droops, the scapula being displaced downward and forward and separated from the spine and its inner border is oblique from below and within upward and outward. In raising the arm the scapula remains applied to the chest and moves outward as a whole. If the shoulder is elevated it

Fig. 4 Diagrammatic representation of displacement of the right scapula when the upper extremity was extended horizontally at the side.

than usual and it approaches the middle line, the inner border of the scapula passing obliquely from above and without downward and inward as if the bone were suspended at its upper inner angle by the elevator muscle of the scapula. When the inferior third of the trapezius is paralyzed the symptoms are much the same as those attending paralysis of the middle third, but in intensified degree. The scapula recedes from the spine, the acromion is depressed, the clavicle is prominent and the supraclavicular fossa is marked.

In the presence of disease of the posterior external branch of the spinal accessory nerve the sterno-mastoid also would be involved, while disease of the anterior internal branch would be attended with disturbance in the functions of the soft palate, the pharynx, the larynx and in the rhythm of the heart.

I wish to report three cases seen at the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases

in which the serratus and the trapezius were paralyzed, two in the service of Dr. S. Weir Mitchell, and one in that of Dr. Wharton Sinkler, to both of whom I am indebted for the privilege of making this use of them.

CASE 1.—M. J., a widow, 53 years old, was admitted to the hospital Jan. 29, 1901, when the following history was elicited: In May, 1900, hysterectomy had been performed for the removal of a fibroid tumor of the uterus, and the patient was kept in bed for four weeks. On the third day after the operation she complained of pain above the right clavicle, which persisted for three weeks and was worse at night. In the fourth week after the operation, on the third day that the patient was up, the nurse noticed a peculiarity of the right scapula, whose inferior angle was displaced. For several months the deformity became progressively more marked and thereafter it remained stationary. From the time of the operation the patient was more or less well able to comb her hair than previously, and her disability had grown gradually worse. For three months there had been some numbness in the fingers of both hands.

and directed inward and backward. The median border of the scapula passed obliquely upward and outward and a band apparently of muscular tissue (rhomboids) could be seen passing from this border in its lower third obliquely upward and inward, to be inserted into spines of the dorsal vertebrae. Above this was a slight depression, which was contributed to by the displacement backward, inward and upward of the inferior angle of the scapula. These features are exhibited in the photographs shown in Figs. 1 and 2, the first of which was obtained when the patient first presented herself, and the second about two months later. At first when the right upper extremity was elevated to the horizontal at the side the median border of the right scapula rode across the median line (Fig. 3), the rotation of the inferior angle becoming less from the action of the muscles attached to the upper portion of the median border, and making a depression measuring 42 mm. at its greatest depth at the inferior angle of the scapula. The deformity is exhibited diagrammatically in Fig. 4.

After two months of treatment with electricity and massage the median border of the right scapula, especi-

Fig. 5.—Displacement of the right scapula when the upper extremity was extended horizontally at the side, after two months of treatment.

Muscular power was quite well preserved in the right upper extremity, but the member was readily fatigued and suffered somewhat from want of fixation of the scapula. After sewing and writing particularly, burning pain appeared in the right shoulder. There was some pain also in the back. The patient was pallid and complained of a sense of weakness in the abdomen as if its contents were falling. The appetite was impaired, the bowels constipated. The tongue was coated and the patient was annoyed by a bitter, coppery taste. There was no nausea or vomiting, but a sense of swimming in the head, followed by a feeling of pressure. The patient thought herself nervous, being readily agitated and easily worried. She suffered at times from slight headache and also from slight tremor.

When the patient stood erect the spine was quite straight. The right shoulder was higher than the left, and the inferior angle of the right scapula at about the level of the spine of the sixth dorsal vertebra was slightly displaced from the chest

Fig. 6.—Displacement of the right scapula when the upper extremity was elevated at the side to an angle of about 75°.

ally the superior internal angle still approached the spine when the right arm was raised to the horizontal, but to a less degree than before becoming parallel with the spine when the arm was in the horizontal position (Fig. 5).

At first the patient was able to elevate the entire right upper extremity scarcely beyond the horizontal at the side, while there was no difficulty in elevating the left arm to a vertical position. Later, when the right arm at the side was continued upward from the horizontal, the superior internal angle of the scapula remained fixed and the inferior angle was rotated outward, but the right arm could not be raised entirely to the vertical position, but only to an angle of about 65 or 70 degrees with the horizontal. This is imperfectly shown in Fig. 6. When the arm was placed in the vertical position with artificial aid it could be held there for a brief period.

When the arms after having been held out horizontally at the side, were rotated horizontally forward, the median border of the scapula receded from the chest-wall (Fig. 7), giving rise to a depression 52 millimeters deep (Fig. 8). When the upper extremities were held horizontally in front, as in the act of pushing, the displacement became more marked posteriorly, although the scapula was removed from the spine. The greatest measurement of the resulting concavity in this position was 50 mm. (Fig. 9). When this last movement was made a bundle of muscular fibers was raised from the chest, passing downward and outward from the inferior angle of the scapula, and leaving a shallow depression above and without, apparently in the muscular mass attached to the lower third of the lateral border of the scapula. When these efforts were made with the arms some twitching could be observed in the triceps.

The muscular reflexes were scarcely as pronounced on

elicited normal responses in the supraspinatus, infraspinatus, deltoid, rhomboids and the latissimus dorsi, with degenerative reaction and slight faradic response in the upper portion of the trapezius and no response whatever to galvanism or faradaism in the lower portion of the trapezius. Despite persistent effort the serratus magnus could not be isolated.

The patient was right-handed and conscious of the weakness in the right upper extremity since the operation. The grasp measured by the dynamometer proved less vigorous on the right than on the left. The greatest difficulty consisted in bringing the shoulder, and therefore, the arm toward the head or

Line of vertebral column

Line of vertebral column

Fig. 8.—Depression caused by recession of the median border of the right scapula from the chest wall when the upper extremity was held horizontally in front.

Fig. 9.—Depression caused by recession of the median border of the right scapula from the chest wall when the upper extremity was held horizontally in front as in the act of pushing.

Fig. 7.—Displacement of the right scapula when the upper extremity was held horizontally in front.

the right as on the left in the scapular region, as well as in the arm, particularly in the region of atrophy below the oblique muscular band passing from the scapula to the spine. A tap over the upper part of the infraspinatus caused the arm to be abducted, while a tap over the middle of the same bunch caused the arm to be rotated inward. A tap on the supraspinatus caused the shoulder to be raised and a tap below the outer extremity of the spine of the scapula caused the arm to be adducted. There was tenderness on percussion and on pressure over the superior angle of the scapula, more marked on the right.

The right arm and forearm appeared distinctly smaller than the left, although by measurement the circumference of the right arm was found to be between  $7\frac{3}{4}$  and 8 inches, and that of the left arm between  $7\frac{7}{8}$  and  $8\frac{1}{4}$  inches and that of the right forearm below the elbow  $7\frac{1}{2}$  inches and of the left forearm  $7\frac{3}{4}$  inches. Electric examination kindly made by Dr. H. P. Boyer

the middle line or the opposite side. Sensibility was entirely preserved all about the right scapula and the adjacent spine. The knee-jerks were extremely sensitive, active, and marked. Ankle clonus could not be elicited. The action of the heart was rhythmic, its sounds clear, the second being relatively accentuated at the right base. The radial artery was small and the tension moderate. The urine was of amber color, of neutral reaction, 1024 in specific gravity, free from albumin and sugar and it contained only a few epithelial and blood cells.

The accompanying photographs exhibit fairly well the position of the scapula under varying circumstances and the accompanying diagrams exhibit the relation of the inferior angle of the scapula with the vertebral column in different positions of the arm.

On account of the obvious local wasting the condition was at first believed to be one of paralysis of the trapezius and this view was subsequently confirmed by the results of the electric examination. The deformity, how-

ever, is so typical of paralysis of the serratus magnus that although we were unable to demonstrate the presence of degenerative electric reaction in this muscle, there seems to be little doubt that it also is involved in the morbid process. The patient gave a previous history of rheumatic pains at different times in the course of the preceding five or six years, but inasmuch as the symptoms had developed only in the sequence of an operation in which I believe the Trendelenburg position was used, and in which the parts affected might readily have been subjected to pressure, I am inclined to think that her condition arose from inflammation of branches of the spinal accessory or of the cervical plexus and the long thoracic resulting therefrom.

CASE 2.—T. H., an iron painter, unmarried, white, 28 years old, was admitted to the Orthopedic Hospital and Infirmary for Nervous Diseases Jan. 4, 1900, complaining of pain at the nape of the neck and in the occipital region on the left side, which was constantly present, though worse paroxysmally. There was also jerking to and from the right, which was relieved by the application of an ice-bag. The head, under ordinary circumstances, was held constantly deflected toward the right. Sometimes pain was present over the entire head.

Fig. 10.—Situation of cicatrices on the left side of the neck.

Sleep was disturbed at times in consequence of the pain.

On inquiry it was learned that in April, 1897, the man had been seized with sharp, shooting pain below and behind the left half of the inferior maxilla, extending to the nape of the neck, to the occiput, to the left side of the head and to the left brow. In a short while the head began to be jerked toward the right and at times to be fixed, facing toward the right. An operation was performed in January, 1898, a piece of the nerve supplying the left sterno-mastoid (three-quarters of an inch) being excised. The nerve was also stretched, and, according to the patient's statement the ends were united, but as to the accuracy of this there may be reasonable doubt. No relief followed. About April, 1898, the left trapezius muscle or the supplying nerve was operated upon and paralysis of the left arm followed, with impaired sensibility, which persisted until the succeeding August. Some weakness was still present in this member when the patient came under observation. Improvement in the pain, the jerking and the stiffness began slowly to take place in the sequence of the second operation, and the patient was measurably comfortable from August, 1898, to about June, 1899. Since this last date, however, he

had grown gradually worse, and since October he had been incapacitated for his work.

The patient presented two cicatrices on the left side of the neck, one 7 cm. long, below the ear, along the anterior margin of the sterno-mastoid muscle, the other 9 cm. long along the anterior border of the trapezius. (Fig. 10.) The interval between the muscles near the clavicle and the shoulder was painful on pressure. The lines of the cicatrices exhibited marked diminution in sensibility, both tactile and painful, growing less as one receded from them. Localization also was poor, impressions being referred sometimes to the ear, at other times toward the clavicle. Sensibility on the left half of the chest to below the level of the nipple was less acute than on the right, also on the left arm than on the right.

Fig. 11.—Areas of hypesthesia, ventral aspect.

arm, although at times it was less acute on the right forearm than on the left forearm. (Figs. 11 and 12.) Sometimes a single impression was felt as two, but in different situations—sometimes simultaneously, sometimes successively. There was increased rapidity of breathing, the respiration being 38 per minute at one time, and 48 per minute at another observation, and there was want of synchronousness and range in the movements of the two sides of the chest, the left rising earlier and expanding more fully than the right. Breathing, further, was somewhat labored, particularly on the left, where the auxiliary muscles were drawn upon. There was some fibrillary tremor in the muscles of the left side of the neck. The scapula occupied a winged attitude and there was apparent absence of the rhomboids on the left, giving rise to a distinct depression between the median border of the scapula and the spine.

Electric examination disclosed degenerative reaction in the left trapezius, while all of the other muscles responded promptly to faradism. A greater faradic current, however, was required to induce contraction of the left trapezius. The circumference of the right arm was 24 cm., that of the left 23. The circumference of the right forearm below the elbow was

24 cm., that of the left 23 cm. The grasp of the right hand was more vigorous than that of the left. Examination of the fields of vision by Dr. A. G. Thomson disclosed contraction, but no reversal. There was no lesion of the fundus. The knee-jerks were preserved. The action of the heart was rhythmic, the sound clear.

In the family history the only noteworthy point was the death of the father possibly from paralysis agitans. Of interest in the personal history was the fact that the patient had influenza prior to the onset of this trouble. This attack left him weak and prostrated, both nervously and physically. In his work he used mineral and graphite paints mostly, but so far as he knew he had never suffered from metallic poisoning. There was also no blue line at the margin of the gums. The man had had an attack of gonorrhea, but so far as he knew he had escaped syphilis. He partook of alcoholics, tea and coffee, with considerable freedom. He had suffered a fracture

Fig. 12 Areas of hypesthesia, dorsal aspect.

of the right leg at the age of 23 by a fall from a bridge 20 feet high. There had been no other mental or physical shock.

The accompanying diagrams illustrate the distribution of the impaired sensibility and also the situation and relative size of the cicatrices on the side of the neck.

In this case also the condition was originally looked upon as one of paralysis of the trapezius, but less attention was paid to this as the patient was more urgently desirous of relief from the distressing spasmodic condition of the head. On subsequent reflection, however, it seems probable that in addition to the trapezius and the rhomboid, the serratus magnus also was paralyzed. We had hoped to secure a photograph of the patient, but he evidently became alarmed by the suggestion of a repetition of the electric examination, which had not proved a source of enjoyment, and on going out for a walk he failed to return. Whether or not the torticollis was in

any way due to the preceding attack of grip can not, of course, be determined, but the possibility is not to be ignored. That the trapezius and the serratus were then paralyzed seems unlikely, and it is far more probable that this condition followed injury or division of their respective nerves in the course of the operations on the neck. The hyperesthesia of irregular distribution is strongly suggestive of hysteria, as was in some respects also the general demeanor of the patient.

CASE 3.—G. H., a girl, 14 years old, presented herself at the hospital on Jan. 17, 1901, with the statement that following an attack of diphtheria four months previously the mother had noticed a peculiar attitude of the right scapula, which stood off from the chest when the shoulder was elevated. Several weeks later pain appeared on the posterior aspect of the scapula, where there was also tenderness. The shoulder could be retracted, and the deformity resulting on voluntary effort was thought to be due to weakness of the trapezius at least. The patient was unable to carry heavy weights or to lift heavy articles or to hold them with her right hand. At times there was pain on movement of the right arm referred to the shoulder. There was some tenderness also in front of the head of the radius. There was no apparent wasting, no fascicular twitching and the reflexes were all preserved. Station was steady, the knee-jerks were preserved, and the grasp of the right hand was more vigorous than that of the left. The action of the heart was rhythmic and its sounds were clear. The appetite was moderate, the bowels were regular and sleep was fairly good. Menstruation was regular, painful and moderate. The parents were well, as were also one brother and two sisters. Two brothers had died in convulsions, and one sister from inflammation of the brain. The patient had had measles at 7 months, whooping cough at 2 years, mumps, and also acute rheumatism at 12 years. She had suffered no traumatism, and drank three cups of coffee daily and no tea.

The patient was seen but once and a detailed study of her case was not made. As indicated, the condition was thought to be due to paralysis of the trapezius, resulting from inflammation of the supplying nerves as a complication or sequel of diphtheria. The striking and characteristic displacement of the scapula, however, makes it probable that the serratus also was parietic.

There is some difference of opinion as to whether the trapezius is innervated solely by the spinal accessory nerve, or additionally by the branches of the cervical plexus. The first and the third of the cases here recorded would seem to lend support to the latter view, inasmuch as one would expect a lesion of the spinal accessory nerve to be attended with paralysis also of the sterno-mastoid, but of which there was in neither of these cases any evidence. On the other hand, one can, of course, conceive of a lesion of branches for the trapezius rather than of the trunk of the spinal accessory at a point beyond the giving off of the branches for the sterno-mastoid muscle. In the second case, in which there was no reason to doubt the existence of a lesion of the spinal accessory nerve, both the trapezius and the sterno-mastoid were affected.

**Cortical Center for the Functions of the Stomach.**—Sollier locates the stomach center in the parietal lobe of the brain, and describes in the *Revue Neurologique* of November 30 a case which he thinks confirms this localization. A boy of 11 was hit on the head with a pickax and was unconscious for a week, with no medical care. He was then trephined, and the coma continued for six days longer, although he took a little liquid food. Then he roused and his prodigious appetite and perfect digestion of the enormous quantities he ate, are accepted by Sollier as evidence that the stomach center had been stimulated to hyperactivity by the trauma and resulting abscess just in front of it. The boulimia gradually subsided in the course of the third month.

## DEMENTIA PRECEDING AND FOLLOWING INEBRIETY.\*

T. D. CROTHERS, M.D.  
HARTFORD, CONN.

A study of the early history of inebriates, particularly of the period preceding the use of spirits, indicates the presence of psychosis, and frequently, degrees of dementia which are unrecognized at that time, but later develop into the drink symptoms.

In persons with a traceable heredity and history of degenerative parents, neuro-psychopathies are easily recognized, but in others who have no hereditary history and seem well up to the beginning of the drink period, previous psychoses have not been studied or recognized.

The theory prevails in most circles of medical literature that the onset of inebriety is a mere chance condition, or an accident which might have been prevented, and is largely under the control of the person. There has been no recognition of an earlier preliminary stage leading up to the alcoholic psychoses. This failure has resulted in confusion and conflict of theory and treatment, with consequent quack remedies and charlatan means for cure and prevention. When this early preliminary stage is examined in persons without any hereditary history, many distinct neuro-psychoses appear associated with changes of character, conduct and physical vigor.

A grouping of some of these conditions will be of interest and throw light on the mysteries which surround the history of the cases. In a general study it would appear that traumatic and chemical injuries are often followed by the use of spirits. Of traumatic causes, early injuries, such as blows and falls on the head, broken legs or contused wounds, with periods of invalidism, more or less severe, are most common. Many persons have a history of such injuries, attended with unconsciousness, great feebleness, slow recovery, and much debility and pain, with nervousness; they suffer from distinct changes in health and vigor. When these causes occur before puberty, this period is often followed by a disappearance or interruption of all the symptoms enumerated. If they occur after puberty, in early manhood, often complex neuroses follow, which lead up to inebriety. Cases of this class may be outlined in the following examples:

A boy, 10 years old, in previous good health, received a concussion from a fall, and after a long convalescence suffered from morbid fears when on high places, and was extremely sensitive to every possible danger from falls and other injuries. At puberty these fears developed into hysteric states of alarm at falling from wagons or from windows of houses which he was in. From this he slowly recovered, and later began to use spirits to give him courage to walk over a bridge on the street he lived in.

In a second example, a young boy of 18 suffered from contused wounds in a runaway accident. He was unconscious, and afterwards suffered from great nervousness, never regaining his customary strength, and showing extraordinary timidity for a long time. Then he began to use spirits, and this nervousness passed away.

A class of injuries in which great mental excitement precedes and is associated with some accident, frequently induce the use of spirits. Thus, a healthy man was in great peril from drowning, and escaped with but slight

injury and shock. The effect of the psychical shock was diminished vigor and strength, which continued for a few months, and then he became a drug-taker and later used spirits.

In another case, two men, both temperate and well, were severely shaken by a railroad accident. The alarm and sudden peril of impending death so impressed them that for a time they were partially paralyzed. A long period of invalidism followed, ending in both using spirits and drugs.

Many very marked cases have been reported of persons who from sudden profound grief at the loss of friends or members of their family, have become invalids, and afterwards developed inebriety. Sudden overwhelming joy has likewise produced profound disturbances of the co-ordinating centers, and afterwards culminated in inebriety. These traumatic causes include almost every possible injury in which there is associated with the physical injury great mental disturbances and depressions. Common injuries associated with drains upon the system, such as protracted hemorrhage or mental strains following pain and suffering, leave an impress on the nerve centers which can be traced in changes that develop spirit and drug-taking.

Many cases which have histories of sudden, unexpected development of the drink psychosis can be referred back to fevers, inflammations and acute diseases which have left a profound impression on the nervous system. Thus, a typhoid or pneumonia, with a long period of convalescence, marked by distinct mental symptoms and extreme prostration, impairs the vigor and leaves entailments which develop the drink psychosis. Sunstroke and heatstroke are also causes which seem to alter and change the normal rhythm and vigor of life, leading to the same results.

It is claimed that a large majority of nervous cases treated with alcohol have developed spirit or drug psychoses in later life, particularly persons who had suffered injuries or diseases which were followed by great exhaustion and long convalescence. In such cases dementia is marked, but it is difficult to say whether the dementia following from alcohol was due entirely to the alcohol given as a remedy for the neurosis or to the injury produced by the disease, but at all events their frequency and intimate association point to cause and effect.

A second class of causes which are becoming more and more apparent from careful researches may be termed chemical or autogenetic. The chemical poisons are intoxications from alcohol or drugs. The profound stupor and delirium which follow from an excessive dose of alcohol taken for the first time may so profoundly impress the system as to leave it permanently injured. Many instances are recorded of persons whose invalidism and debility dated from the first intoxication. They may never use spirits again until middle life or later, but the mental and physical impression dating from the first intoxication has been so pronounced that there can be no doubt of its persistence. Cases like the following are not uncommon:

A young man at the time of his graduation from college became profoundly intoxicated. The depression, both physical and mental, following this event continued for years. Then he was given spirits as a medicine in typhoid fever. From this time he became an inebriate.

A second case was that of a temperate man who, after a snake bite, consented to drink large quantities of spirits until he became intoxicated. He recovered, but was

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

never well after this, always complaining of debility and mental dread of disease and death. Some years after he suddenly began to use spirits to excess, and became an inebriate.

Cases are not infrequent of persons who have taken large quantities of spirits without a visible exciting cause, and become suddenly intoxicated, recovering with great mental depression, and ever after showing changes of character and conduct that finally developed into inebriety. A few cases have been mentioned where profound narcotics from opium has resulted in some obscure changes and final inebriety. A dose of arsenic taken by mistake producing gastritis, was followed by a long period of indigestion and invalidism, and finally ended in spirit excess. No doubt there are many cases of this kind in which the early causes are overlooked, but from the few cases reported it is evident that a severe poisoning of the system from either vegetable or mineral drugs not infrequently precipitates states of degeneration and dementias which lead up to drug and spirit taking.

Another field of early poisonous influences has been traced to the formation of toxins in the body. Persons who have neglected many of the common rules of living, and who suffer continuously from what is termed dyspepsia and imperfect nourishment, frequently develop states of mental debility which go on in a progressive march to inebriety or some complex form of insanity.

Cases like the following are often noted: A temperate man, from neglect and defective eating, became a hypochondriac with delusions about food; he suffered from an attack of fever and began to use spirits to great excess, and died from delirium tremens.

Persons who overwork, and are in constant mental strain without proper rest, and who neglect the nutrition of the body, frequently have periods of invalidism and defects which lead up to inebriety. The underfed and the overfed who neglect the ordinary rules of living are subject to auto-intoxications and auto-infections which profoundly impress the organism and develop some disease later. In the study of a large number of cases, many of these common conditions of poisoning have been prominent in early life and have caused debility and invalidism, which has finally culminated in the drink craze. Some of these cases develop a drug-taking mania with the hope of curing real or imaginary diseases, accompanied with fears of death and intense desire to avoid pain and discomfort. They are often tea and coffee drinkers, and have fads in regard to foods, with intense introspection and constant watchfulness to discover signs of oncoming disease. They frequently develop inebriety. In such cases there are many symptoms of dementia, with mental change and debility. In some instances this is apparent in certain organic changes of the body; in others it is seen in the general decline and failure of the functional activities. The mental vigor and power of restoration grows less, and exhaustion increases and becomes more and more prominent.

In the second class of causes, namely, dementia coming from spirits taken regularly in small quantities, or at intervals to excess, the symptoms are more pronounced and more readily treated. The man who uses spirits continuously to excess will always exhibit changes of both the mental and physical organism, which at first may be slight, but which increase steadily. The delusion that it is possible for any one to drink regularly any length of time and not suffer from it is dispelled by the study of such persons.

Dr. Clouston writes: "I am confident that no man who uses spirits continuously, even though he is never intoxicated or never appears to have any mental impairment in his social and business relations, is physiologically changed for the worse. If the practice goes on for ten years serious organic changes will follow, and in most cases, in much less time."

Many persons use spirits daily and boast of their strength to drink in moderation and not be injured. This is a delusion. They may possess inherent strength which will resist degeneration for a time and mask the symptoms, but in the end the dementia which is inevitable from this source will appear. Many such persons carry on business along accustomed lines without much change, but their real condition is apparent when called to take up some original work or engage in some activities requiring originality, spontaneity and vigor. Usually some intercurrent disease appears, with fatal termination, or some form of invalidism which is ascribed to other than the real causes.

The evidence of dementia is more apparent in so-called moderate drinkers who use spirits continuously than in those who take spirits to excess at times and follow indulgence with a free interval of sobriety.

There is in persons who use spirits continuously, or occasionally to excess, a tendency to assume one of three forms of degeneration: 1. The periodical drinker belongs to the epileptoid class where distinct exacerbations and explosions of nerve energy are apparent. 2. The continuous or so-called moderate drinker is of the parietic class. 3. The irregular, uncertain user of spirits is of the insane or maniacal class with a constitutional tendency to mania and melancholy. In all these cases there is a progressive dementia, sometimes masked; at others there are apparent degrees in which both character and conduct undergo a progressive change.

Many of these persons while following accustomed lines of thought and conduct seem very little impaired, yet a careful examination will show more and more automatic activity, less spontaneity and less original work. If thrown out of their accustomed line of life the feebleness is at once apparent. Their inability to take up new subjects, or to act wisely upon a new class of facts is often startling. Thus, a so-called moderate drinker who apparently conducts his business with skill and judgment, will show idiocy in his estimate of new questions and new requirements. Some of the most extraordinary and unexplained acts of men previously sound and wise in their accustomed line of work are explained in this way. Thus, a business man and continuous drinker whose business was conducted with skill and acumen accepted the position of counsel and adviser to a large estate, the investments of which were new in his experience. His imbecility and childishness wrecked the property, and his responsibility was settled in the courts to his great disadvantage. The chagrin and sorrow of this event caused his mental breakdown and death. In reality he was demented before he took up this new business, and yet his friends did not recognize the fact.

Almost innumerable instances occur of the failure of moderate or occasionally excessive users of spirits to adapt themselves to new conditions with the same judgment exercised in their accustomed line of work.

The epileptoid cases have distinct periods of egoism and over-confidence in their ability to grasp new situations and to control new events. This is a most suspicious symptom, particularly when associated with the constant use of spirits or drugs.

In the epileptoid cases there are distinct paroxysms during which the demented states are readily recognized. Sometimes these paroxysms last many days or weeks before recovery. The mistake is made by friends who suppose that recovery leaves the brain intact, and capable of acting normally and as wisely as before. If the man continues his old business and family relations, taking them up after the attack in about the same way, there is no opportunity to show the damage done, because the work is largely automatic. The mental failure and demented condition would be apparent if these persons were required to take up some new work or enter upon new conditions of life and living. Then the excessive nervousness, feebleness of judgment and instability of connected thought or act would appear.

In the maniacal and melancholic cases, there is the same uncertainty of thought and act, with extreme sensitiveness to conditions and surroundings and exaggerated conceptions of events and their influence. In many of these cases there are symptoms of malaria, rheumatism, neurasthenia and heart failure, with general muscular and mental fatigue. These conditions suggest spirits as a remedy, which only intensifies the very conditions they seek to prevent. They are in reality stages of dementia which should be recognized and treated by change of surroundings, habits of living, and conduct generally.

Associated with the continuous or occasional use of spirits there are always found changes of nutrition. The metabolism of the body is always broken up and the presence of toxins and toxemias are common in all cases. How far these poisons contribute to the dementias present it is difficult to determine, but that they exist and have an influence can not be doubted.

It is now recognized that notwithstanding the apparent immunity which is provoked in the system by the regular use of spirits, there is a continuous shock or concussion to the higher brain centers as an effect of alcohol.

These concussions are literally anesthetics and paralyzants, which depress and alter nerve activities, at the same time breaking up the nutrition, so that in addition to palsy and depression, there is starvation and weakness. The effect of the continuous use will be really an intensification and persistency of effect from which recovery becomes more and more doubtful. A certain number of these cases go on to develop well-marked symptoms of dementia, which is described often as "alcoholic epilepsy" or "general paresis" from alcoholism, or "alcoholic insanity," with mania and melancholia. These are names for the extreme stages of the disease.

Most of the cases die from intercurrent disease before these stages become prominent. Pneumonia and acute inflammations of the liver and kidneys, with heart failure, are the more common forms of terminations, but are indirectly caused by the use of spirits.

In many cases cerebral hemorrhages occur, either causing death or partial paralysis, which continues during the rest of life. Accidents are responsible for a large number of deaths. The paralysis extends to the senses, impairing their power and thus increasing the liability to injury, and when such injury occurs the resisting power of the system is so impaired that full recovery seldom follows.

The craze for drugs and medicines in these drink cases is another phase of dementia. Persons of previously good, sound judgment in other matters will show infantile credulity and confidence in strange methods

and unreasonable means that promise help and freedom from pain. This is seen in the unusual demand for certain proprietary drugs which contain spirits, opium, or other narcotics. After a period of the use of certain drugs they are abandoned and others take their place. Such persons, if wealthy, make long tours to different watering-places, health resorts and sanitariums in search of health, and are always dissatisfied. In the meantime they continue the use of spirits at intervals or constantly. There is always a failure in the system, a state of unrest and discomfort, which they seek to overcome by chemical means. Dementia is also apparent in the gambling spirit and craze for making money rapidly, dealing in stocks, and new ventures or short cuts to fortune. This in a drinking man is often pronounced, the same as the erotic impulse manifest in sexual intrigues and infidelities. These and various other symptoms are seldom recognized as having a pathological basis, but are always explained by moral theories.

The moderate drinker, who is a gambler, or sensualist, or delusional politician, is a dement, and should be recognized as such. The moderate drinker who is delirious at times, or intensely melancholy with suicidal symptoms, is also a dement, and should be treated as such.

In the treatment of these cases, the removal of alcohol is of the first importance, but this will not always cure. Serious damage has been done, and the use of alcohol is not a cause, but often a symptom, and as a symptom it indicates greater intensity and increase of the causes.

The presence of poisons and starvation should at once suggest the remedies which are not found in drugs or specifics, but in eliminatives and nutrients, with continuous hygienic care. The nutrition of the body must be corrected, and all sources of poison removed, and long continued nerve and brain rest be secured.

The exhaustion and general debility occurring in persons who have previously been very actively engaged in mental or muscular work, may be the first stage of dementia, and alcohol given as a tonic may have special degenerative action on the brain and nerves, and become a powerful exciting cause.

If there is a tendency to any special form of psychosis, alcohol will increase it by bringing new poisons and destroying the vigor of the body, as well as the functional power or repair and elimination.

States of cerebraesthesia and general exhaustion treated with compounds of spirits, as wines and beers, frequently develop into inebriety and other marked psychoses. Hence alcohol in any form is a dangerous remedy, and its so-called tonic effects in debility are doubtful and perilously uncertain. Any long continued use of alcohol should suggest dementia as a most natural sequence, and the treatment must be based on this prognosis.

The general facts I wish to make prominent are:

1. States of dementia precede inebriety and become both predisposing and exciting causes.
2. The continuous or occasional use of spirits is often followed by dementia in many forms.
3. All use of spirits reveals certain degenerative tendencies along the marked lines. viz., the paretic, the maniacal, and the demented or idiotic types.
4. Alcohol as a tonic is dangerous by increasing the toxins and conditions of poisons with starvation, and should never be used in brain and nerve psychoses or any other condition of neurosis.
5. Alcoholic psychosis in every form should be care-

fully studied before treatment can be given with any degree of accuracy.

## DISCUSSION.

Dr. C. A. DREW, State Farm, Mass.—I am in hearty sympathy with Dr. Crothers' paper. I believe that by habitual drinking a man's inhibitory power becomes impaired, particularly that associated with the higher functions of the brain, which we term the moral sense. I believe the habitual moderate drinker will think differently and act differently, where ethical considerations are involved, than he would think and act were he not a moderate drinker of alcoholics. This is a manifestation of the lesser subtle effect of regularly repeated small quantities of alcohol circulating through a fairly good brain. When weaker brain cells are daily subject to the stimulating or anesthetizing influence of alcohol, according to the dose, there is no question about the resulting condition deserving the name of dementia. More than a thousand cases were committed for drunkenness to the prison department of the State Farm in Massachusetts last year. While many of these men are intelligent, in the common sense, they all seem lacking in moral sense; hardly one ever intended to be anything more than a moderate drinker. These men seldom blame themselves. They have unlimited faith that they can drink or let it alone. They do not appreciate their own weakness nor their obligations to others. I think it is fair and scientific to call these men demented. There were 77 men patients admitted to the Massachusetts State Asylum for Insane Criminals during the last fiscal year; 64 of the 77 cases admitted were free drinkers. No reliable history could be obtained from 7, while 6 were abstainers or only moderate drinkers. There was a clear history of intemperate fathers in 38 of these cases, and 10 of the cases testified that their mothers had been hard drinkers. One of the 6 temperate cases was a moral imbecile whose father and mother were both hard drinkers, the former having suicided while insane. We occasionally meet an imbecile child of an intemperate father and mother who has no taste for alcohol, tobacco or other drugs. This deviation from the rule may perhaps be due to the revolt of a developing organism against super-saturation while in the embryo.

Dr. CROTHERS, closing the discussion—The subject of inebriety will probably receive a fuller discussion at future sessions of the Association. Every year brings us nearer to this great dark wall of alcoholism, and neurosis which can not much longer be neglected by physicians.

## DYSPEPTIC ASTHMA.\*

MAX EINHORN, M.D.

Professor of Medicine at the New York Post-Graduate Medical School.

NEW YORK CITY.

Asthma due to digestive disturbances was first described by Henoch<sup>1</sup> under the name of asthma dyspepticum. The original communication of this clinician referred to the occurrence of the condition during acute digestive disturbances in children. His cases all ran under alarming symptoms—the dyspnea being of a high degree and attended with cyanosis and cold extremities—and failed to improve under the ordinary stimulants, but entirely recovered after a treatment directed against the disturbances of the digestive tract. In his paper Henoch accepts Traube's explanation for the dyspeptic origin of asthma, which is as follows: "The gastric irritation causes reflexly a vasomotor contraction of the small arteries, which explains the cold extremities, the imperceptible pulse, the congestion in the venous system and in the right heart, cyanosis, accumulation of carbon dioxide in the blood and as a consequence thereof the frequent dyspneic respiration."

A short while afterwards Silbermann<sup>2</sup> described four cases of dyspeptic asthma which were identical with

those of Henoch. Silbermann assumes the presence of a paralysis of the inhibitory fibers of the vagus as well as of the heart itself. On this account the ventricles, especially the left, can not empty themselves completely, and as a result of this there is a stagnation in the pulmonary circulation and the right side of the heart. Owing to the disturbance of circulation the blood becomes overcharged with carbon dioxide, which in turn causes the dyspnea, cyanosis and cold extremities. Edema of the lungs need not be present, as the paralysis of the left ventricle is only of a moderate degree.

While the two writers just mentioned discussed the subject of acute asthma in children, Barrié<sup>3</sup> was the first to describe cases of dyspeptic asthma of a more or less chronic nature in adults. He first showed the intimate relations existing between stomach, heart and lungs, and entered in detail upon our subject of dyspeptic asthma. He says: "Cardiac complications, the result of certain affections of the stomach or bile ducts, present a very great variety in their symptomatology and prognosis. Sometimes there are only slight disturbances in the frequency, intensity or regularity of the heart-beat; sometimes the symptoms approximate those of angina pectoris; at other times the symptoms refer both to the heart and to the lungs; dyspnea then sets in, which may amount even to suffocation, and at the same time dilatation of the right ventricle of the heart may be diagnosed. The disorders are characterized by a respiratory embarrassment varying from the merest feeling of oppression to true dyspnea; at times even we have orthopnea, which may lead to suffocation. Whatever the clinical form may be, the respiratory difficulty appears immediately after meals, the quantity of food having no influence upon its appearance. With predisposed individuals the smallest morsel suffices to evoke an attack. Chomel, who observed the dyspnea of certain dyspeptics, says: 'The patients, after having taken merely a few spoonfuls of soup, experience a respiratory embarrassment of a more or less severe nature lasting throughout the whole time of digestion.' We have here then a very special kind of dyspnea, independent of any distension of the stomach by gas during digestion, differing also from the transient and purely mechanical kind of oppression, observed in large eaters after a copious meal. It is not in the respiratory tract that the obstacle is to be looked for, but in the pulmonary circulation. However that may be, the air hunger, not being appeased, soon produces inexpressible anguish with imminent asphyxia. The face, at first pale, is covered with cold perspiration and becomes purple, especially around the eyes, lips and cheeks. The extremities are cold and livid; the pulse is accelerated, soft and compressible. The pupils are dilated; speech is impossible; the body immobile, excepting the thorax, which works incessantly, and the patient appears in great danger, as if he were about to succumb to an attack of suffocation. Digestive troubles being the cause of these cardio-pulmonary symptoms, therapeutic intervention must be directed to the stomach. We have two indications to meet: 1, to put the organ at rest; 2, to supply it with food of an easily digestible nature. A milk diet answers most admirably both these purposes."

Lauterbach<sup>4</sup> next described a case of dyspeptic asthma. The patient had been suffering for three years from severe dyspnea, occurring as a rule from three to four hours after meals, preceded usually by malaise, vertigo and occasionally even by fainting spells. These attacks lasted one-half to one hour and ceased after patient vomited. In dyspeptic asthma, according to Lauterbach, we

\* Read before the Buffalo Academy of Medicine, Oct. 8, 1901.

have to deal with a reflex disturbance of the cardiac action and especially a temporary inability of the left ventricle to perform its work, a condition that is present also in cardiac asthma, but only as the result of a grave organic lesion. The dyspnea accompanying the attacks of dyspeptic asthma is the result of a stasis of the pulmonary circulation due to the insufficiency of the left ventricle.

Oppler<sup>5</sup> likewise reports a case of dyspeptic asthma. Patient suffered from hyperchlohydria and hypersecretion. In the fasting condition there was found in the stomach a small quantity of bile. A rational treatment of the stomach—lavage—was accompanied by the disappearance of the asthmatic attacks.

Boas<sup>6</sup> published an important communication on this subject. He described eleven cases, four of a light and seven of a severe nature. In the latter group were included: 1, individuals with disturbances of the circulatory and respiratory apparatus, and 2, such in whom the thoracic organs were normal. In both classes, however, a connection between the attack and the ingestion of food could be demonstrated.

Ehrlich<sup>7</sup> reported a case of dyspeptic asthma in a patient who had previously suffered from regular asthma caused by nasal polypi. After removal of the polyps the asthma disappeared. Following a grave indiscretion in diet the new type of asthma developed, characterized by the occurrence of an attack immediately after eating. It began with a painful feeling of oppression in the region of the stomach and did not subside until the patient had vomited everything, either voluntarily or against his will. The heart in this case was not normal and treatment had to be directed toward that organ as well as the stomach. Lavage of the stomach and strophanthus effected a cure.

Murdoch<sup>8</sup> describes a form of chronic dyspeptic asthma characterized by great shortness of breath on slight exertion, the condition being not paroxysmal but continuous. It occurs in patients suffering from gastrointestinal diseases without any abnormal condition of the heart, lungs or kidneys, sufficient to account for it, and yields readily to treatment directed against the existing dyspepsia. Murdoch reports five cases, in three of which achylia existed.

Among the cases described by Barrié one was also characterized by the occurrence of asthma on slight exertion after a meal. He says: "Since four months this young girl complains of a feeling of oppression occurring immediately after meals and lasting several hours, which obliges her to stop all work; at times the attacks are brought on by walking; she must then sit down or rest for nearly a quarter of an hour."

Dyspeptic asthma being a condition that is not so very rare and of great importance for the practitioner, is well worthy of consideration. A report of my own observations on this topic will possibly be of interest. Although Boas and others have described among their cases of dyspeptic asthma patients who were also troubled with cardiac or pulmonary affections, I am of the opinion that we should reserve the term "dyspeptic asthma" for cases free from any involvement of the chest organs and in which the affection is in distinct connection with the digestive apparatus. Wherever there are cardiac or pulmonary troubles it is best not to group these cases in our category. Even if the symptoms be more predominant shortly after meals, the principal lesion causing the dyspnea in these instances lies in the affected thoracic organ and not in the stomach. It is quite natural, and

it may be observed in a great number of cases of cardiac or pulmonary asthma that during gastric digestion, especially after a good-sized meal, there is more dyspnea present.

In the last few years I have observed 31 cases of dyspeptic asthma in which the chest organs were apparently in normal condition. These cases can conveniently be classed into two main groups: 1, cases in which dyspeptic asthma appears in an acute form, periodically; 2, cases in which dyspeptic asthma assumes a more chronic type.

The first group is characterized by the occurrence of attacks of asthma at more or less prolonged intervals, either without an apparently preceding cause or after distinct excesses in eating, drinking, smoking or after undue excitement. The attack is usually of a very severe type, often assuming alarming symptoms—extreme dyspnea, cyanosis, almost collapse. A good instance of this group is represented by the following case:

Cyrus P., 33 years old, has been troubled for the past two years with frequent attacks of dyspnea. They usually occur at night before retiring. The patient becomes aware of a feeling of constriction, starting in the epigastric region and extending along the chest. Very soon after this there is great difficulty in breathing—dyspnea. The heart action is accelerated; the extremities become cold and the forehead is covered with perspiration. The patient gasps for air and feels as if he is going to die. He constantly makes efforts to expel gas by mouth or anus, and succeeds only from time to time. This affords him very slight momentary relief. After the struggle has lasted about half an hour, intense retching sets in which, after a while, terminates in spontaneous or involuntary vomiting. The latter marks the end of the attack. The patient then breathes much easier, and after a few minutes falls into a sound sleep. Such attacks appear about once in a fortnight. Often it occurs after some festivity at which patient took a luxurious dinner. Patient smokes a great deal, but has otherwise good habits.

The examination of the chest organs did not reveal anything abnormal. The stomach was slightly dilated, extending down to the navel, and showed a condition of moderate hyperchlohydria. The urine was normal and the knee-reflex present. The treatment consisted in the application of bromids, alkalies and a rational diet. The attacks decreased in number and severity, but did not entirely disappear.

The second group, that of chronic dyspeptic asthma, embraces the larger number of cases, and may again be divided into two separate categories: (a) cases in which the attacks of asthma appear quite soon after meals, either without any particular provocation or after some slight exertion; (b) cases in which the attacks usually occur two or three hours after meals, either spontaneously or again after some exertion—walking, etc. In a certain number of the latter category the attacks can be checked by partaking of a small amount of food.

Cases belonging to category (a), of group 2, resemble very much true angina pectoris, which is so often encountered in arteriosclerosis of the coronary arteries. Their differentiation from the latter is often very difficult. For even in true angina pectoris, at the beginning there will be attacks without any discoverable lesions of the heart or blood vessels. Such cases may for a long time appear as dyspeptic asthma until all of a sudden there are distinct signs indicating the heart involvement, as, for instance, a sudden appearance of albumin in the urine or irregularity of the pulse, etc. I may be permitted to report a case of this kind:

Mrs. Jeannette A., about 67 years old, had been troubled for the last two to three years with frequently-occurring attacks of dyspnea on exertion soon after meals. Thus the patient would

have an attack of dyspnea if she walked a certain number of blocks a half hour or so after a meal; climbing of stairs would also be liable to produce the same result. As a rule the attack would not be very severe nor last long. The patient, after resting about fifteen or twenty five minutes, would feel relieved. It appeared that the amount of nourishment taken was also of paramount importance with regard to the occurrence of the attacks. Large meals with exertion soon afterward were more liable to produce an attack than walking after a small meal. In the fasting condition or several hours after a meal the patient never had an attack even after walking greater distances. At first the chest organs, particularly the heart, were found perfectly normal.

A year or so later, however, the attacks appeared more frequently and with greater intensity, and now occasionally there was irregularity of the pulse, and albumin was sometimes found in the urine in very small quantities. The heart now was found to be somewhat enlarged to the right. One of the attacks later on was so intense that patient fell into a condition of collapse. A few weeks later there was another attack followed by edema of the lungs, from which, however, patient rallied after energetic stimulation—dry cups, camphor injections, ether, etc. Ultimately (about a month later), however, she succumbed to another attack of edema of the lungs.

True cases of dyspeptic asthma belonging to group 2, category (a), are the following:

CASE 1.—April, 1896, James H., 56 years old, has been complaining for the last year of poor appetite, bloated feeling, constipation and attacks of dyspnea shortly after meals, especially after some slight exertion. These attacks vary in intensity, sometimes being quite severe, at other times again of a slight nature; when severe, there is also a feeling of fear present as if the patient were going to die. A thorough examination revealed no abnormalities whatever in the chest organs. The stomach was not dilated, but the chemical examination showed total absence of gastric juice and all other signs characteristic of achylia gastrica. Patient was told to live on a principally vegetarian diet and was also given fluid extract of condurango, and fluid extract of cascara sagrada. Very soon after instituting this regimen patient began to improve, gradually gained in weight and was free not only from the dyspeptic symptoms but also from the attacks of dyspnea. Patient since then has felt perfectly well up to date, which means a period of five years; the achylia, however, has persisted.

CASE 2.—David M., 35 years old, began to complain two and a half years ago of disturbances of digestion. He had a feeling of tension in his stomach, and suffered from headaches and constipation. For about a year he has complained of attacks of dyspnea either a half-hour after large meals or when his stomach is empty—i. e., a short time before meals. He claims that it is difficult for him to get air during the attack; after bringing up gas he feels somewhat relieved. Before going to bed and during the night patient frequently has similar attacks. He himself uses the expression "forced breathing" to denote the mode of respiration. The attack usually lasts about an hour. Patient also says that besides the dyspnea he experiences pain on the right side a little above the ensiform process. His appetite has always been good, but there is much eructation of gas. He has lost 22 pounds and weighs now 170 pounds. Heart and lungs are normal, stomach is not enlarged, its lower margin lying three finger widths above the navel. The urine contains neither sugar nor albumin. An examination of the stomach contents reveals normal conditions.

The differentiation between dyspeptic asthma belonging to this category and true angina pectoris is not always easy. As a rule, however, cases of dyspeptic asthma are amenable to treatment; that means that a rational régime with regard to the digestive apparatus is followed by good results. These cases also are often capable of a permanent cure. Cases of angina pectoris, however, caused by cardiac lesions—if the latter are not manifest—are much less amenable to treatment, and if improved, the amelioration is only transient.

The following case is mentioned as a good illustration of attacks, like those in category (b), occurring two or three hours after meals, either spontaneous or again after some exertion:

William H. A., 46 years old, has been complaining for the last six months of some distress in the upper part of the abdomen, appearing usually about two or three hours after meals and lasting for an hour or two. Frequently the distress would be accompanied by attacks of dyspnea so that patient would not be able to move and would have to keep perfectly quiet, struggling for breath. The attack of dyspnea would last from one-half to three-quarters of an hour, when retching would ensue and be followed by vomiting. This would bring relief of the distress as well as of the dyspnea. Similar attacks occasionally occurred about 12 or 1 a. m. at night, awaking patient in the midst of a profound sleep.

A thorough examination did not reveal any apparent abnormal conditions existing in the chest. The urine was free from sugar and albumin. The gastric secretion, however, indicated a condition of intense hyperchlorhydria.

Treatment instituted against this disturbance of the stomach very soon relieved the patient of all his troubles. He has remained well for the last two years, having no more attacks.

A good instance of the dyspeptic asthma being checked by the partaking of food is the following:

Leopold K., about 54 years old, has been complaining for the last ten years of an intense burning in the stomach appearing an hour or two after meals. At this time any slight exertion would bring on an attack of quite intense dyspnea. The partaking of food or drink would very soon check the attack and patient would be able to continue his work. Here also aside from hyperchlorhydria nothing abnormal was found and a rational treatment of the latter condition greatly diminished the paroxysms of dyspnea.

The remaining cases of dyspeptic asthma observed by me I beg to submit in a concise form in the accompanying table.

TABLE OF THE REMAINING CASES OF DYSPEPTIC ASTHMA.

| Group. | No. | Name.         | Age. | Condition of stomach secretion.      | Position of abdominal organs.   |
|--------|-----|---------------|------|--------------------------------------|---------------------------------|
| 1.     | 1   | Daniel M.     | 36   | Hyperchlorhydria and hypersecretion. | Enteroptosis, ren mob. dext.    |
| "      | 2   | Miss F. P.    | 32   | "                                    | Enteroptosis, ren mob. dext.    |
| "      | 3   | Wm. H. A.     | 52   | Hyperchlorhydria                     | Normal.                         |
| "      | 4   | Adolf E.      | 48   | Euchlorhydria                        | Normal.                         |
| 2 (a)  | 5   | Dr. W. F. R.  | 40   | "                                    | Normal.                         |
| "      | 6   | Louis G.      | 36   | Achylia gastrica                     | Normal.                         |
| "      | 7   | Wm. F.        | 33   | Achylia gastrica                     | Hepatoptosis.                   |
| "      | 8   | Mrs. A. K.    | 36   | Hyperchlorhydria                     | Normal.                         |
| "      | 9   | Mrs. F. H.    | 50   | Euchlorhydria                        | Normal.                         |
| "      | 10  | Alex. G.      | 27   | "                                    | Hepatoptosis.                   |
| "      | 11  | Joe H.        | 40   | Euchlorhydria                        | Normal.                         |
| "      | 12  | Louis R.      | 37   | "                                    | Normal.                         |
| "      | 13  | Herm. L.      | 49   | "                                    | Hepatoptosis.                   |
| "      | 14  | H. H.         | 50   | Achylia gastrica                     | Normal.                         |
| "      | 15  | Abraham M.    | 46   | "                                    | Hepatoptosis.                   |
| "      | 16  | Ferd. B.      | 43   | "                                    | Normal.                         |
| "      | 17  | Frank F.      | 42   | Hyperchlorhydria                     | Normal.                         |
| "      | 18  | Carl H.       | 37   | Hyperchlorhydria                     | Atonia ventriculi gastroptosis. |
| "      | 19  | Mrs. W. R. R. | 35   | "                                    | Normal.                         |
| "      | 20  | J. I. S.      | 55   | Hyperchlorhydria                     | Normal.                         |
| "      | 21  | M. W. M.      | 63   | "                                    | Atonia ventriculi.              |
| 2 (b)  | 22  | Mrs. A. R.    | 42   | "                                    | Normal.                         |
| "      | 23  | Herm. M.      | 53   | Hyperchlorhydria                     | Normal.                         |
| "      | 24  | John K.       | 55   | Hyperchlorhydria                     | Normal.                         |
| "      | 25  | H. W.         | 58   | Hyperchlorhydria                     | Normal.                         |
| "      | 26  | Abr. P.       | 36   | Hyperchlorhydria                     | Hepatoptosis.                   |

A great many of my cases of dyspeptic asthma have been examined with regard to the secretory condition of the stomach. Although no constant anomalies were found, it is noteworthy that a considerable number of the patients suffered from achylia gastrica; hyperchlorhydria likewise was often encountered. In both these conditions a rational treatment of the gastric affection was frequently crowned with favorable results as far as the disappearance of asthma was concerned. The explanation why two such contrary conditions may pro-

duce the same phenomenon may be found in the fact that in both probably an undue irritation of the gastric mucosa takes place. In hyperchlorhydria it is the hyperacid gastric juice, in achylia the mechanically unchanged coarse particles of food, which irritate the mucous membrane of the stomach and thus reflexly the vagus fibers.

In those cases in which the gastric secretion is more or less normal it will be necessary to assume a condition of hyperesthesia of the stomach in order to explain the cause of the asthma. This was already done by Boas.

In my paper on "Floating Liver,"<sup>9</sup> I have drawn attention to the frequent occurrence of asthma in these cases. In fact, a considerable number of patients with floating liver manifest no other symptoms aside from the existing asthma. The cases of dyspeptic asthma referred to in this paper have all been examined with regard to the existence of any abnormal position of the abdominal organs. Floating liver was noted in a considerable number (5) of these cases. There is hardly any doubt in my mind but that the abnormal position of the liver, dragging the diaphragm downward, is the cause of the existing dyspeptic asthma in these cases.

The treatment must be directed first toward relieving any existing disorders of the digestive tract; second, toward correcting any abnormal position of the abdominal organs, principally the liver. A regular mode of life, avoidance of too much tobacco and alcoholic drinks, also of too much mental worry and strain is always of importance. By paying attention to these points the majority of cases of dyspeptic asthma will not only be temporarily relieved, but often radically cured.

## THE IMMEDIATE DIAGNOSIS OF BLASTOMYCETIC DERMATITIS.

A. W. BRAYTON, M.D.

Professor of Clinical Dermatology, Syphilology and Clinical Medicine. In the Medical College of Indiana; Vice-President of the College; President of the Indiana State Medical Society; Editor of the Indiana Medical Journal, etc.

INDIANAPOLIS, IND.

As regards location, Chicago has developed the greatest number of the cases of blastomycetic dermatitis so far reported. Dr. Hyde's list published in the Proceedings of the American Dermatological Association held in Washington, May, 1900, includes 17 cases, as follows: Gilchrist-Duhring, 1; Busse-Buschke, 2; Gilchrist-Stakes, 3; Wells-Senn, 4; Hessler, 5; Hyde-Hektoen, 7; Anthony-Herzog, 8; Coates, 9; Owens-Eisendrath-Reedy, 10; Brayton, 11; Hyde-Ricketts, 12; Hyde-Ricketts, 13; Montgomery-Ricketts, 14; Montgomery-Ricketts, 15; Montgomery, 16; Dyer, 17.

To these I now add a second case, under my observa-

tion from April 17 to May 31, at which time the patient was discharged cured. Other cases were no doubt reported at the May meeting of the American Dermatological Association, Chicago, May 31 and June 1, as the program states that Dr. F. H. Montgomery, Chicago, had two additional cases to report, and in company with Dr. J. W. Walker, a report of a previously recorded case with systemic infection, death and autopsy.

The disease occupied much attention at the Washington meeting, and opinions varied as to the etiology of the disease, those not having studied cases either clinically, or by sections and cultures, being skeptical as to the relations of the yeast, which is so uniformly found in the cases so far studied. As to the literature, a summary may be found in the last edition of Dr. Hyde's treatise on Diseases of the Skin. Dr. Senn devotes a chapter of some fourteen pages, with illustrations of the histo-pathologic sections and of the yeast plant, in the recent edition of his Principles of Surgery. The report of Dr. Gilchrist, Johns Hopkins University, to whom we are indebted for the name blastomycetic dermatitis, is of the highest interest, as it constitutes the primary monograph on the disease in this country.

Aside from the Chicago cases, 3 are now reported from Indianapolis: the case of Dr. Robert Hessler;<sup>1</sup> my first case,<sup>2</sup> exhibited at the Atlantic City meeting by photographs, microscopic sections and cultures of the yeast plant, and I now am able to present the details of another case, with some notes on the immediate diagnosis. Dr. Dyer<sup>3</sup> reports a case from New Orleans, and Dr. F. J. Shepherd, before the recent meeting of the American Dermatological Association in Chicago, reported a case which was cured by iodine.

The papers read at the Washington meeting, taken in connection with the discussions which followed, represent fairly the opinions of our dermatologists as to the natural history, the clinical appearance, the micro-pathology and the parasitic etiology of this disease. We have first to consider whether the score or more of cases cited, over half of which have occurred in Chicago, really warrant the presentation of a new dermatosis to the profession. And second, are the cases so far described tuberculosis of the skin? Finally the inquiry as to whether the cases, or some of them at least, are not complicated with syphilis, has been considered.

In the discussion of the subject at Washington. Drs. J. C. White and J. T. Bowen, both of Boston, and Drs. W. A. Pusey and Joseph Zeisler, both of Chicago, were inclined to regard the case as tuberculosis of the skin, the blastomycetic element being only a secondary complication. Dr. Bowen and Dr. Zeisler contended that the clinical evidence of the pure cultures of the organism being capable of producing by inoculation a similar disease in animals, is not yet sufficiently established.

Dr. J. C. Johnson was inclined to agree with Drs. Bowen and Zeisler, because of the unusual picture of exudative inflammation with pus, existing side by side with productive tubercles, presented by blastomycetic dermatitis. He further believed that the failure of inoculation to produce a condition which we could recognize as blastomycetic dermatitis, according to Koch's laws, does not prove anything. "We cannot," said Dr. Johnson, "by any known means, no matter what form of bacillus we use, produce at will any type of cutaneous tuberculosis with which we are familiar." He also said

1. Ind. Med. Jour., August, 1898.

2. Ibid., April, 1900.

3. Jour. Cutan. and Venereal Dis., January, 1901.

that Dr. Wm. H. Welch had recently stated to him that he had no doubt as to the pathogenicity of the blastomycetes, and in deference to Dr. Welch's authority, he desired to withdraw any objection he may have made to the causal relationship of the fungus to blastomycetic dermatitis.

That the disease is a pathologic entity was earnestly contended by Dr. Gilchrist. He asserted that the organism is present in every case, that pure cultures have been obtained from the majority of cases, and that similar pathologic processes have been reproduced in animals. The clinical features of all the cases described are fairly constant, and it seems decidedly proven that the disease, whether considered from a clinical, pathologic or bacteriologic standpoint, stands apart from other diseases of the skin. In no one of the Chicago cases is the disease to be regarded as syphilis with blastomycosis implanted on it, as there was absence of syphilitic history, and the histologic picture was not that of syphilis, but of blastomycetic dermatitis. Dr. Gilchrist also quotes the observation of Dr. Hyde and others, that potassium iodid exerts a curative action in the disease.

In view of all the recorded studies of the known cases, made by Drs. Gilchrist, Hyde, Hektoen, Montgomery and others, we are perfectly justified in regarding this disease as an entity, and while it is possible that it may occur on the skin of patients suffering from either syphilis or tuberculosis, there is no reason for regarding it as any one of the protean manifestations of either of these diseases. Recognizing the disease, then, as an entity and using the name given by Dr. Gilchrist of blastomycetic dermatitis, some observations on its immediate diagnosis will be presented.

In any given case of ulcerative lesions of the skin we have in mind the possibility of its being syphilitic, tubercular, epitheliomatous or blastomycetic. Tertiary syphilitic ulcerations, subsequent to the breaking down of gummata, may resemble blastomycetic disease of the skin. But here we may rely upon the clinical history, the presence of other lesions in the body and the general hyperplasia of the lymphatic glands. We may also resort to the therapeutic differentiation by the use of the iodids; however, these are thought by Hyde, Shepherd and others to inhibit the growth of the blastomycetes.

The affections most likely to be mistaken for blastomycosis are tuberculosis and epithelioma. In tuberculosis of the skin, represented by the lupus of the early writers before the etiology of tuberculosis was known, we have a more penetrating disease, invading tissues irrespective of their anatomic structure, and rarely starting from multiple foci. Lupus, moreover, is a disease of childhood almost exclusively, though persisting into mature life. It is to be remembered, however, that the case primarily referred to Dr. Gilchrist and studied so extensively by him, was regarded by Dr. Duhring as a "typical chronic scrofuloderma verrucosa," and that the first case described by Dr. Montgomery had been seen by Dr. Pusey, Chicago, several years before, and photographed with the label "tuberculosis verrucosa cutis."

Finally as to epithelioma, the sections of my first case of blastomycetic dermatitis—No. 10 of Dr. Hyde's list—were mistaken by casual observers for ordinary epithelioma of the skin. Cancer of the skin is a lesion rarely seen before the age of 40, and indeed the greater number of cases occur more nearly at 50. Of the 17 cases of blastomycosis tabulated by Dr. Hyde, 8 are

under 40 years of age; my 1st case was 50, and my 2d, 27. The age limit of cancer is an important point in diagnosis, lupus being a disease of childhood. Cancer of the skin usually occurs after 40, while syphilis and probably blastomycosis may be found at any age, as in other diseases due to direct contact with the virus producing them.

Again, epithelioma has its points of anatomic predilection to an extent not at all characteristic of blastomycetic disease, as is shown by a mere glance down Dr. Hyde's column of the regions invaded. Cancer of the skin begins at some common center and in its course invades the tissues met, regardless of their structure and function, and mercilessly following the lymphatic channels wherever they lead. Cancer usually is represented by a single primary ulcer with a regular indurated base and margins not at all characteristic of blastomycosis. The glandular involvement as a rule is absent in the yeast-caused growth, while in cancer sooner or later the glands are involved in the process. Blastomycetic disease is primarily a disease of the skin—a dermatitis slowly creeping and destroying, healing and scarring over, as the process extends. Dr. Hyde's column showing the duration of the disease, includes cases of 4, 5, 7, 11 and 20 years' progress, limited, perhaps, as was the Wells-Senn case, for ten years or more to the back of a single hand.

Thus far, no two cases of blastomycosis have occurred in the same family; there is no history of hereditary tendency as is frequent with epithelioma. As far as we know neither epithelioma nor blastomycosis has been transferred from one member of a family to another, although blastomycosis is evidently distinctly auto-inoculable, as is shown in the history of my second case.

These general considerations of syphilis, tuberculosis, epithelioma and blastomycosis are certainly of value in the clinical and immediate diagnosis. But there is yet another feature of blastomycosis upon which we may be justified in laying stress, and that is the persistent pain of progressive blastomycosis, unlike any of the discomfort attending the other ulcerous lesions which resemble it in general appearance. The edges of these ragged and irregular ulcers are in a constant state of inflammation, extending perhaps from one-fourth to one-half an inch into the skin not yet breaking down. The symptoms are heat, redness, swelling and pain—a gnawing, burning and persistent pain, intensified at night, preventing sleep, leading to the use of opiates, and only relieved by the destruction of the invaded margins with caustic, or the actual cautery, or by the knife. The knife, the hot iron, the application of carbolic acid followed by the concentrated acid nitrate of mercury, gives immediate relief, or at least as soon as the pain of the burning has been subdued by appropriate dressings. Let the process be incomplete, however, as occurred several times in case number 11 of Dr. Hyde's list while under the care of various physicians during the eighteen months' progress of the disease, and, with the further growth of the organism on one side or the other of the primary lesion, the intolerable pain again begins and the patient is willing to submit to a repetition of the destructive process, even begging to have the affected member amputated.

I know of no observer who has been so fortunate as to see the lesions of blastomycetic dermatitis early in their growth. From the history given by the patients and from the study of cases presenting a series of lesions in various stages of growth, the following conclusions

are tenable and are illustrated in my second case. If, on any part of the body, notably the exposed parts, as the hands, face and feet, a portion of the skin presents pustules followed by small crater-like ulcers which coalesce causing progressive destruction of the skin, blastomycosis may be suspected. At first the patient thinks the lesions are small boils, and resorts to poultices. Upon consulting the physician, the lesions are mistaken for boils, possibly for lupus, or syphilis, or epithelioma, and appropriate treatment given according to the diagnosis. If regarded as lupus or cancer, the physician may cauterize the lesions with the actual or the chemical cautery, and no doubt in the past many cases have been cured in this way, for the disease can in no sense be regarded as new to the human species, and indeed, is probably as old as cancer, lupus or syphilis.

Whether or not the patient has lived in a region where the conditions for yeast growth are favorable, that is, in low moist countries or localities where the ordinary yeasts of commerce are abundant, would seem to have no weight in diagnosis, but the failure to find cases in our coast cities, notably in Boston and New York, and the abnormal number of cases observed in Chicago, would seem to favor the suggestion of Drs. Hyde and Fordyce that the fungus has a local distribution. Those affected, as shown by Dr. Hyde's list, are people in contact with the soil and its products; they are laborers, carpenters, etc. But again, these people constitute the larger part of the population, and so the occupation has little or no significance. Whether the infection takes place through the unbroken skin is not settled, but certainly, as in common pustular acne, the primary infection may be by way of the sebaceous ducts. The organism by its toxins, incites a folliculitis with obstruction of the outlet of the gland and penetration of the gland sac. Therefore the occurrence of multiple acneoid pustules in close proximity to each other occurring in unusual localities, unsymmetrically distributed and followed by necrosis and punctiform excavated ulcers, should call attention to the probability of blastomycosis.

Dr. Wm. T. S. Dodds, Indianapolis, who has kindly taken charge of the microscopic work and bacteriopathologic studies upon the cases falling under my observation, has made the following notes in regard to the microscopic diagnosis, which are here appended.

In the immediate diagnosis of blastomycetic dermatitis, the microscope is one of our greatest aids. The recognition of the yeast cells in the tissues is as easy as the demonstration of the tinea in the epithelial scales and hair, and can be performed in about the same length of time.

A bit of tissue taken from the advancing margins, is macerated in a 20 to 30 per cent. potassium hydrate solution for five to ten minutes, or until the blood cells and extraneous bacteria are destroyed. The pus taken from a small abscess and treated in a like manner will answer the same purpose. It is well, in order to avoid confusing oil droplets with the yeast plant, to first wash the tissue in ether for a short time; this, however, is unnecessary in experienced hands, because the yeast cell is very easily differentiated. The potash solution has no action upon the yeast cells and they stand out in the macerated material as doubly contoured highly refractory bodies from 5 to 20 microns in diameter. They are almost always in the budding stage and it is not uncommon to find several organisms in the same field. The concise method used in our laboratory for the demonstration of the yeast plant in the tissue is as follows:

1. Secure a small bit of tissue from the advancing margins.
2. Place this tissue upon a glass slide and wash in ether, 2 to 5 minutes.

3. Macerate in the potash solution, using a cover slip to assist in dissolving the tissue, 5 to 10 minutes.

4. Examine the specimen under the microscope, using a 1/6 to 1/12 objective.

This method will be found convenient, sufficient and conclusive. It can be used at the time of operation and will determine the amount of tissue which should be removed.

The cultivation in pure culture of the yeast from the diseased tissue is easily performed, if care is exercised in obtaining the planting. Pure cultures are often obtained in the first tube inoculated. Beer-wort gelatin makes the best medium for work of this kind. The colonies are easily recognized because of their large size, white fluffy appearance and clean-cut margins. Cultures can be obtained directly from the tissue upon Loeffler's blood serum tubes, such as are used in the bacteriologic work for diphtheria.

NOTE.—Since the above was written the author has observed another case referred for diagnosis, August 1, by Dr. H. R. Lowder, of Bloomfield, Ind. The growth was the size of the palm, on the skin of a man of 60. It had begun as a folliculitis two years before. The lesion was proliferative, consisting of papillary masses the size of match sticks  $\frac{1}{8}$  to  $\frac{1}{4}$  inch long, matted together and flattened by continuous bandaging. The appearance was that of Dr. P. A. Morrow's case of tuberculous papillomatosa cutis reported in the *Jour. Cut. and Venereal Diseases*, of October and December, 1888. The case was seen by Drs. F. B. Wynn and N. E. Jobes. The yeast plant was at once isolated by Dr. Dodds, not only from several parts of the lesion but from follicles resembling acne one-half inch from the growth—a finding of very considerable interest. We have sections of the growth and the pure cultures of the yeast. At the margin was an elevated, inflamed and very painful border. No central scar tissue was present. Syphilis and epithelioma were excluded.

## SUDDEN AND TEMPORARY MENTAL ABERRATION—UNCONSCIOUS AUTOMATISM— TEMPORARY IRRESPONSIBLE STATES.

SAMUEL AYRES, M.D.

PITTSBURG, PA.

The problems in psychology are numerous and fascinating, and many are yet unsolved. A man may be able to carry on a considerable conversation to-day, during which he betrays only slight peculiarities, perhaps only some exaggeration in speech; or, unless he is watched closely, he may not appear out of the ordinary; to-morrow he declares he has no recollection of the conversation. But what a loophole this hiatus may offer to one dissatisfied with his contract, or to one on the wrong side of the market who wishes to repudiate the order to his broker of the previous day, or to the one who wants to curse or annihilate his enemy!

It is a fact, though, that there are certain individuals who at times perform certain automatic acts, or say certain things, or are seized with sudden delusions or hallucinations, who, after a period of a few minutes, or a few hours, or a few days, suddenly recover their usual cerebration, seem quite natural in all respects, and have no recollection whatever of these acts, though they may recall the delusions or hallucinations as one remembers a dream in the waking state.

The numerous instances recorded in the newspapers of the sudden and unaccountable disappearance of individuals, and their subsequent discovery at distant parts of the country, wholly unable to explain such transition, are by no means all fictitious. Many of these are too well authenticated to be doubted. Some are perhaps in

that state known as double consciousness. Others may be in the epileptic psychical equivalent, while others may perhaps become suddenly insane from injuries to the head or from other causes. The cases I shall relate do not include those of prolonged suspension of normal consciousness, which have so mystified the laity, but are those as the title describes, of sudden and temporary mental aberration especially characterized by the performance of unconscious automatic acts.

The great interest attaching to these cases, and the importance of their recognition, are especially twofold: First, such individuals are liable to commit serious crimes, such as murder, arson or other felonies, while in this morbid condition, and to be totally unconscious of and wholly irresponsible for such crimes. Secondly, these morbid states should be so thoroughly studied that the deliberate criminal could not succeed in urging them as a cloak for his crime, and thus escape just punishment by law.

One of the cases I have to describe is an epileptic, who, in the psychical equivalent for a period of three days, suddenly left his work, traveled several miles, procured a revolver, shot himself in the left chest, was immediately taken to a hospital and did not recover his usual mental state for two days later, being absolutely unaware during this time of what he had done, or what he had suffered.

The other is that of a man about 35 years of age, under treatment for a neurasthenic condition, resulting from alcoholism and syphilis. This man during the course of treatment disobeyed orders, and began drinking liquor one afternoon at 1 o'clock, and after 4 o'clock did not recall a thing he had done until the following morning. From the statements of his wife, though, it appeared that he went home that evening about 5 o'clock, left two evening papers upon the bed, walked out of the house and presumably down town. He probably continued drinking in the evening, lost his watch and money, and returned home about 12 o'clock the same night and threatened his wife, but did not seriously abuse her. He went to bed soon after, and awoke, as previously stated, rational in the morning. To a casual observer he would not have been recognized as being intoxicated.

The third case was that of a man who, after severe muscular exertion and physical strain resulting from a footrace, developed a delusion that at the close of the race there was a runner still ahead of him, though he had outdistanced all competitors and won the race. At this time and immediately after the race he had severe pain on the top of his head, with a high pulse. This man would at times subsequently have perfectly lucid intervals of variable duration, and would as suddenly, especially toward the evening, become irrational and threaten to kill his wife. The passing from the lucid to the irrational period was instantaneous and vice versa, and during my examination I watched him closely lest he would have one of his lapses, for he was not to be trusted in such condition. I might add there was no litigation involved in any of these cases.

CASE 1.—March 18, 1899. Mr. T. B., age 30, was married ten years, three children. Brass worker, and previous to that, worked at steam and electricity. No history of head injury. Father's health good. Mother living at 59 and in good health. Has two half-brothers in good health. Habits have always been temperate in regard to liquor; used tobacco rather freely.

General health was good up to 22½ years of age, about eight years ago. At that time he began to have attacks of the following character. While sitting talking in the room he would

get up and walk across the room, and move or turn a chair upside down, or do some such ridiculous thing, and would return and sit down again. Says he was conscious of what he was doing at the time, but not able to prevent it. These peculiar acts would occur about once or twice daily. At this time he was a general utility man in the machine shop. Automatic acts of this character continued for about one year, then became more frequent. At one time he picked the baby up to take it downstairs to its mother, when a spell came on and he dropped the baby on the stairs. He was entirely unconscious of this act until two months after when his wife told him of it. At another time, a week later, during an attack, he dropped the baby on the floor. For two years past he has occasionally gotten up at night in an attack, dressed himself, and then returned to bed with his clothes on. At another time he suddenly struck a friend with whom he went to a picnic. One night he went over to the bed of his children and jumped on the bed and also assaulted violently his wife. The neighbors came in and took him for safety to the lock-up.

In June, 1898, he was working near Pittsburg in a machine shop. On Friday, at 3 p. m., while working at his machine, he reached up and stopped it, took his hat and coat and went to the depot. There he took a train for Allegheny, a distance of 15 miles, wandered around, possibly in the park, though he does not remember about this; shot himself through the left chest, just above the heart, the bullet passing entirely through the body.

He was removed to the Allegheny General Hospital. He he was not conscious of what had occurred until the following Sunday. The lapse of consciousness began at 3 p. m. on Friday, and continued up to some time on Sunday. After recovering from the effects of the gunshot wound, he began to have more pronounced attacks in which he would fall down and lose consciousness. These attacks seemed not to be convulsive. The attacks after this were nearly all nocturnal and regularly epileptic in character. He returned to work and continued up to Sept. 15, 1898. His condition became so dangerous they thought it wise to remove him from home to protect his family. He went voluntarily to the Allegheny County Home on September 15. Here he remained for some months and was then transferred to the Dixmont Insane Asylum, where he had numerous ordinary epileptic attacks, but rarely a psychical equivalent, as I have subsequently learned from Dr. Walker, the resident physician.

CASE 2.—December 9, 1898. Mr. V., 31 years of age, married one year, was in lumber business; confined to office. Former weight was 190 lbs.; present weight, 165 lbs. He was in good health up to three or four years ago, when he drank to excess. Mother's side of family was neurotic. There was a specific history.

Present trouble began three or four years ago. He is very nervous; stomach disordered; sleeps quite well. When he stops drinking for a while head feels thick and dull. Bowels are not very regular. He uses tobacco freely; drinks one cup of tea at meals. Knee-jerk is about normal. Pupils react to light and in accommodation. He has vertigo at times.

Feb. 27, 1899. Called to-day to resume treatment. He has not been so well lately on account of drinking. Three days ago he began drinking whisky freely toward the middle of the day, and by 3 p. m. was thoroughly under the influence, though not staggering drunk. He could walk about quite easily, and thinks from his gait no one could have told that he was under the influence of liquor. At 4 or 5 p. m. he was totally unconscious of what he was doing. He went home, left two newspapers in the upstairs room, and went out of the house and down town again, and never knew that he had been at home. He had no clear recollection after that of what he did for some hours, though he indistinctly recalls the fact that he inquired of a stranger what car to take home at night. He says he went speeding around town, but does not remember where he lost his money and watch. He went home about 12:30 or 1 at night and was inclined to threaten and abuse his wife. He went to bed, and after sleeping until next morning awoke perfectly conscious. Then he learned from his wife of his abusive treatment of her, but he had no recollections of what had

transpired in the interval except as mentioned above, the street-car incident.

**CASE 3.**—July 27, 1898. Mr. M. J. W., age 27, was married nine months. He was a policeman formerly; surveyor at present. Previous health was good. He used liquor to excess up to two years ago, and never used tobacco up to present trouble, and not to excess the last few months; not much tea nor coffee. He had no head injury. In August, 1897, he ran three foot races, the first a mile, the second two and a half miles, and the third three and a fourth miles, and won all of them. At end of last race he was exhausted, and after passing all contestants, still imagined one racer was ahead of him. After race he had slight headache, and pulse 140. Next day he had severe ache over the top of head, and headache irregularly for some time. During fall of last year, about October, he imagined colored people were behind him and would look back suspiciously, no one was really around. He always slept well. About four months ago he fancied some one was too attentive to his wife and he threatened to do them injury. Is quite suspicious. These delusions come suddenly and leave suddenly; in evening more pronounced. He has had some weakness in knees. Knee-jerks are a little exaggerated. Attacks recur about every twenty-four hours, usually in the evenings, and may last an hour or more.

These cases are of some interest from the point of view above stated, and call attention again to the possibility of homicides by persons in irresponsible mental condition. The unique features of the first case lie in the fact that the attempted murder was that of self instead of another, and is without parallel as far as I have been able to learn. It calls up the question as to whether some suicides may not be committed in the psychic equivalent—a very strong inference were the suicide an epileptic.

It should be the duty of all physicians called to testify in murder cases where the mental condition is in question, to inquire most carefully as to the presence of any epileptic tendencies or the occurrence of epileptic attacks; and it should be remembered that the psychic equivalent, as in this case, may precede the ordinary convulsive attack; so that some criminal attacks may be the first evidence of any abnormality in the individual, to be followed later by more convincing proof of the epileptic state. Then again, as pointed out, the malingerer who might attempt to feign this condition should be detected from the history of his case and from a careful examination, if possible, during the simulated seizure. It would certainly be very difficult to uncover the impostor in a feigned psychic equivalent, as the part to be acted requires no particular skill or cunning.

The occurrence of sudden mental aberration in cases like No. 3 is also, I believe, quite uncommon. This result was probably ascribable to the extreme nerve exhaustion or to an altered cerebral circulation, probably congestive, as evidenced by the severe pain on the top of the head. Had this man, on the night after the races, killed his wife, as he was liable to do from some delusion, it would have been a very difficult task at the trial to demonstrate his irresponsibility, owing to the suddenness of the attack. This case should be remembered as an example, rare though it may prove, that great physical strain may be sufficient to temporarily derange the mind.

The alcoholic case, No. 2, though by no means exceptional, reminds us that while a state of alcoholic or drug intoxication does not serve as an excuse for crime, it may be held to extenuate the act. Had this man murdered his wife when he returned home in the evening or at 12 o'clock at night, it would have been done not only without premeditation, but without consciousness per-

haps of the act, as he did not know that he had been at home either during the afternoon or late at night. Normal consciousness seems to have been entirely suspended for a time, during which he was in a state of alcoholic delirium or automatism, without the characteristic alcoholic ataxia. But this is not very uncommon. Some men drink lightly or heavily and at once pass into a state of frenzy or fury, during which they have no recollection of the acts performed at such time.

## RAPID SUGAR TESTING WITH HAINES' AND PURDY'S SOLUTIONS.

WILLIAM H. GERMAN, M.D.

CHICAGO.

A search for sugar and its quantitative estimation are necessary in all routine work of urine examination. The well-known Haines' solution for qualitative testing is so simple and trustworthy as to leave nothing to be desired. One dram of the solution is boiled in a test tube, six to eight drops of urine is added, and the boiling continued. If a bright yellow or red precipitate is obtained, sugar is present. With slight practice, one to two minutes is sufficient to in this way gain decided qualitative data.

The methods in use for quantitative estimation of sugar are generally too slow and cumbersome to be of value to the busy practitioner of medicine. He has

either to be contented with the information obtained from a qualitative test, or send to some laboratory where a specialty is made of urine examinations. A method devised by my assistant, Mr. Carl Irenæus, eliminates the tediousness of the standard methods, and gives rapid and accurate results. The only apparatus required is that shown in the accompanying illustration, viz., a graduated test tube and pipette, and a Bunsen burner or spirit lamp.

When the presence of sugar in the urine has been determined, as by the Haines' test, fill the test tube to the 12 c.c. mark with Purdy's solution, and the pipette to the zero mark with the urine to be tested. Heat the test solution to boiling, and add the urine drop by drop in the test tube, boiling for a few seconds after the addition of each drop, until the blue color has entirely disappeared, trying to decolorize with the smallest possible quantity of urine. If less than 0.2 c.c. of the urine is required to decolorize the test, the urine contains above 4 per cent. of sugar, and should be diluted with an equal volume of water, and the results obtained multiplied by two. The subjoined table gives all ratios of reduction from one-half of 1 per cent. up to 4 per cent., calculated to each quarter per cent., with corresponding grains per ounce.

After slight experience with this method, the time required to make a complete qualitative and quantitative test need not exceed five minutes. This method has been carefully compared with the standard methods of sugar testing, and results have been found fully equal to those obtained by the standard methods. It was used for years by Mr. Irenaus in the laboratory of the late Dr. Charles W. Purdy in all cases where rapid results were required.

| Cubic cm. Urine | Per cent. Sugar. | Gr. per oz. |
|-----------------|------------------|-------------|
| 2               | 4                | 19.2        |
| 225             | 3.75             | 18          |
| 25              | 3.5              | 16.8        |
| 275             | 3.25             | 15.6        |
| 3               | 3                | 14.4        |
| 325             | 2.75             | 13.2        |

## TRAUMATIC ARTERIO-VEINOS ANEURYSMS OF THE SUBCLAVIAN VESSELS.

WITH AN ANALYTICAL STUDY OF FIFTEEN REPORTED CASES, INCLUDING ONE OPERATED UPON.

RUDOLPH MATAS, M.D.  
NEW ORLEANS.

(Concluded from page 247.)

### PRACTICAL CONCLUSIONS.

As a result of the study of the arterio-venous aneurysms of the subclavian vessels which we have summarized in this contribution, we find that this class of injuries can be separated clinically and surgically into three distinct and well-defined groups:

1. The immediately fatal cases in which death follows so quickly after the injury from the effect of the primary hemorrhage and shock that no effective surgical assistance can be rendered. These probably constitute the largest proportion of cases, especially in military practice, though an exact estimate can not be obtained. It is also probable that the vast majority of injuries involving the first and second divisions are fatal primarily, and are to be included in this group, except when the injuries are caused by small projectiles or sharp-pointed weapons.

2. In this second group, primary hemorrhage may be very great, but spontaneous or temporary hemostasis occurs in the syncopeal state, which favors the formation of a provisional thrombus. In this class of cases two events may occur which will profoundly modify the prognosis. In the one case (*a*) secondary bleeding will set in within a few hours or, more often, days—usually within the first week—with disastrous consequences, unless the patient is rescued by prompt operation or other form of intervention. The other alternative (*b*) justifies the formation of the following group.

3. In this group the primary hemorrhage may also be excessive, but, as a rule, is moderate and is readily controlled by pressure, or may be spontaneously arrested as in the second group. More often there is no syncope, because the external hemorrhage is slight. There may be a large hematoma. No secondary hemorrhage occurs, the wound heals up, leaving a well-defined and permanent arterio-venous aneurysm.

The arterio-venous circuit is usually promptly established by direct inosculation between the artery and vein (aneurysmal varix), or by means of an intermediary sac (varicose aneurysm), the fistulous communication between the vessels acting in both cases as a safety-valve by which the dangers of further extravasation are to a large extent permanently avoided.

Rötter, in his paper published in 1893, analyzes 13

cases of stab wound of the subclavian vessels, 5 of which were arterio-venous, including the one which he reports, in which he operated for secondary hemorrhage following an injury to both vessels.

He found that in 6 cases the hemorrhage was spontaneously arrested, and no secondary hemorrhage occurred; but in all of these, secondary traumatic aneurysm developed, which impaired the usefulness of the arm, either partially or completely, and led to grave secondary complications which subsequently imperiled life.

In seven cases, the larger number, repeated secondary hemorrhage occurred, and the result was far more serious, for all these patients except Rötter's—an arterio-venous injury—died, and this one was saved only by prompt and desperate operation undertaken at midnight. As a result of this inquiry, Rötter advocates immediate operation—i. e., ligation of the injured vessels at the bleeding point as quickly as possible after the patient has recovered from primary shock and hemorrhage, without waiting for the appearance of the secondary hemorrhage which might prove fatal. The only objection to Rötter's recommendation is that it is based upon the study of mixed cases of simple arterial and arterio-venous injuries, and not sufficient stress is laid upon the more favorable tendency displayed by the arterio-venous injury when these show an early disposition to form aneurysmal varices.

The relative benignity of arterio-venous aneurysms when fully developed—i. e., when the communication between the artery and the vein has become distinctly and permanently established—has led, as Poincot correctly remarked in 1882, to the general acceptance of a fallacious doctrine that in wounds of a single vessel, such as the subclavian artery, the simultaneous lesion of the satellite vein was a safeguard to the life of a patient.

For instance, Moore,<sup>6</sup> in commenting upon Larrey's case, said the patient's "life appears to have been saved by the singular circumstance that the vein was also pierced by the lance (saber), which wounded the artery. The blood from the latter vessel, when restrained from passing through the external wound, escaped into the vein, and was thus saved to the system until the wound healed." The explanation, says Poincot, is as fantastic as the pretended benignity of the injury is contestable.

If the simultaneous lesion of the artery and vein is apparently less dangerous statistically than injury of the artery alone, this is due to the fact that in many immediately fatal cases the existence of the double injury is not recognized until after death or only in the cases in which the patient survives and the anastomosis has had time to form or an operation has been performed for repeated hemorrhage. Whatever the doubts entertained on the subject, the cases of Will, Rötter, and Veiel alone suffice to prove that the old teaching as to the relative benignity of double injuries is not to be trusted. One fact, however, must be admitted, as we have conclusively shown in our table, and that is that once the arterio-venous connections have been firmly established, these injuries, as a class, are less dangerous to life than the traumatic aneurysms involving the artery alone.

### TREATMENT.

In dealing with these cases practically there are three questions that now present themselves for discussion or consideration: 1. What is the best treatment that can be applied to arrest the primary bleeding at the time of

injury? 2. After the arrest of the primary hemorrhage, and the patient has rallied from the shock, and it is evident that one or both vessels have been injured, shall we proceed immediately to secure the bleeding point, or wait for future developments, hoping that the wound will heal, that no secondary bleeding will occur, and that if it is a double injury a permanent arterio-venous communication will be established? 3. After the existence of an arterio-venous aneurysm is fully established and the wound has apparently healed, shall we consider the patient out of danger and discharge him with this lesion in an active state, trusting to Nature's tolerance of this condition and to the remote possibility that it may be spontaneously cured?

We may now briefly summarize our conclusions on these three points seriatim: The treatment of arterio-venous injuries of the first division of the subclavian need scarcely be considered. The cases of survival after the immediate effects of such an injury must be rare indeed. Nevertheless, wounds inflicted by very small caliber bullets—Letenneur's case—or with narrow-pointed weapons may give rise to comparatively small hemorrhages which, being spontaneously arrested and circumscribed, will end in aneurysmal varices. It is quite possible that in future, cases of this kind in this locality may be more frequently recorded than in the past, especially since the introduction of hard, small-caliber projectiles in modern warfare. It is evident that in this division of the artery no operative treatment is permissible, the danger and magnitude of the intervention overshadow the possible danger of the lesion, which when reduced to the condition of a simple varix, is undoubtedly compatible with a long tolerance and survival.

In dealing with arterio-venous traumatism of the second and third divisions of the subclavian the conditions are different. Here the vessels are comparatively accessible, and notwithstanding the grave and formidable character of the undertaking it is quite possible after the resection of the clavicle, as first suggested by Langenbeck, and practiced by Bergmann, Rötter, Halsted, the author, and others, to bring the vessels into view and to ligate them.

In dealing with the first condition—*i. e.*, a bleeding patient—it is evident that all attempts at radical operation on the spot can not be considered in ordinary circumstances. The first indication, then, is to arrest the bleeding, and this is best done by 1, digital compression over a compress or in the wound; 2, by packing the wound, if it is a penetrating cut, and holding the pack firmly wedged in the wound by suturing the edges of this over the pack; or, 3, by hermetically sealing the wound with a continuous stitch, as Rötter suggests. This procedure, followed by a firm compression bandage, will usually suffice to arrest the external bleeding until the patient is taken to a hospital or other convenient place, where a flat bag, filled with lead shot, and held over the injured area with an elastic bandage, will usually prevent any further primary—external—bleeding.

After the patient has rallied from hemorrhage and shock, then the question arises: Shall we operate and when? Shall we wait for a dangerous, if not fatal, secondary hemorrhage to occur, or prevent this by operation? On this point there are differences of opinion. No one will question the propriety of early intervention in cases of arterial injury with the formation of a large, increasing and *pulsating* hematoma. Here the general principles which have guided the surgeons in the past are applicable with still greater reason. The wounded

vessels must be sought for at the bleeding point if possible. Bergmann's rule in reference to subclavian injuries, confirmed by Le Fort and Poinot, and more recently emphasized by Rötter, in reference to arterio-venous injuries, has become an acknowledged law in this class of cases.

"The ligature of the artery should be performed as soon as the patient has recovered from shock; if possible on the day of the injury; and the vessel should be secured in the wound and tied above and below the injured point."—Rötter. While we recognize the great force of a surgical canon which is based upon sound reason and experience, it must be recognized, with Wedekind and other recent writers, that there are conditions which justify delay, more especially in those cases in which the subclavian wound implicates both vessels.

It must be recognized that even a reasonable suspicion or positive evidence of an injury to both vessels—artery and vein—is not sufficient to justify a suspension of the above stated rule of practice, but that the development of positive signs of an *established* arterio-venous anastomosis does justify delay when the patient can be kept under constant observation and intelligent supervision. But as the signs of arterio-venous anastomosis are often delayed, other criteria must be depended upon to decide the question of intervention or abstention. Of these modifying conditions, the following are probably the most important:

1. The quantity of blood lost in the primary hemorrhage whether profuse, moderate or small.
2. The extent of the subcutaneous hematoma.
3. The fact that the hemorrhage was arrested with difficulty, or ceased spontaneously and completely, after syncope.
4. The tendency to recurrence of early intermediate hemorrhage, "warning hemorrhages," which are the invariable precursors of the more formidable and fatal secondary hemorrhages.
5. The development of positive signs of an established arterio-venous communication.

If the primary hemorrhage is profuse and obstinate; if it tends to recur with the restoration of the circulation after shock; if the hematoma is extensive and progressive, then there can be no hesitation as to the urgency of surgical action, whether the evidence points to a single or a double injury of the associated vessels.

If, on the other hand, the primary bleeding is moderate and is readily controlled by pressure, or ceases spontaneously and completely, and there is no extensive or progressive hematoma; if there is no tendency to bleeding upon the removal of the dressings, then delay—*i. e.*, armed expectation, is permissible. If, in addition to the favorable signs, there is an early development of the signs of an arterio-venous anastomosis, then a conservative attitude is more than ever justifiable, *provided*, always, that the patient can be kept under competent and skilled surgical supervision.—Wedekind.

As to the last point, it is evident that even under the most favorable conditions, and with the most skilful assistance, the ligation of a wounded subclavian is a formidable undertaking, always fraught with great danger, and demanding for its successful accomplishment all the resources of the technique and the cool judgment which come only with long training; and if these are wanting at the time, it is plain that expectancy and palliation, with pressure, rest and ice, is the only conservative course to pursue until the patient has rallied sufficiently to be transported to a place where the necessary conditions for a radical operation can be obtained.

Finally, if the patient survives the first hemorrhage and shock, and there is no recurrence of hemorrhage,

TABULATED STATEMENT OF SEVENTEEN RECORDED CASES OF ARTERIO-VEINOUS ANEURYSMS

| No. | Operator or reporter.                            | Sex and age.         | Nature of injury.                     | Seat of injury.  | Result.   | Primary hemorrhage (syncope).                             | Secondary hemorrhage.                   | Associate or complicating injury.                                      | Date of appearance of aneurysmal signs.                                   |

and the wound heals, with the formation of a simple aneurysmal varix, what is the proper course to pursue? On this phase of the subject it may be safely asserted that the consensus of surgical opinion first formulated thirty-six years ago, when Letenneur's case was discussed at the Société de Chirurgie in 1867, has crys-

tallized in definite form in favor of non-intervention.

The statistics which we furnish in this paper—the most complete list of the reported instances of this rare lesion which has thus far appeared—tend to confirm the arguments of the "let-well-enough-alone" policy, in so far as they demonstrate that in at least 11 of the 15 cases

## OF THE SUBCLAVIAN VESSELS. GATHERED FROM THE LITERATURE (1827-1901).

| Immediate effect of injury on arm.   | Non-operative treatment.  | Operation, if any; date and indication for operation.   | Distant or remote effects of aneurysm on arm.  | Remarks.   |
|--|---|---|--|--|
| Arm icy, pulseless, colorless.   | Pressure, ice, repeated venesection.                                    | No operation.   | Atrophy, paralysis of hand; permanent obliteration of pulse in all arm.  |  |
|  |   | No operation.   |  | Persistence of aneurysmal signs for more than 10 years, for which patient consulted Sanson in 1832.  |
|  |   | No operation.   |  | Discharged "several" weeks later with persistence of aneurysmal signs, clamoring for operation, which Bérard and Diefenbach refused.   |
| None.  | None for primary injury.  | Double ligature third portion on 17th day for aggravation of pain and vascular disturbances.  | After ligature arrested pulsation in arm; returned second day; infection ten days after, and secondary hemorrhage.   | Immediate effects of primary injury not recorded; apparently insignificant; aneurysmal signs and tumor requiring ligature 31 years after primary injury; arterio-venous aneurysm confirmed by autopsy.                                     |
|  |   | None.   | Withered, paralyzed, cold; no sensation; pulse weaker and not synchronous with other side.   | Died of diarrhea, 1554, 7 years after injury, and with persistent aneurysmal symptoms; arterio-venous aneurysm confirmed by autopsy.   |
| Enlarged veins, diminished pulsation; arrest of circulation on elevation of arm. | None recorded.  | None.   | Arm cold, edematous, and pulseless; sloughing of little and ring fingers and inner side of dorsum and palm to ulnocarpal articulation.                         | About 7 months after injury sloughing of hand occurred spontaneously, slough detaching without constitutional symptoms; tumor at site of wound size of walnut; stationary.   |
|  | Boyer's compressor without effect.                                      | None.   |  | Came under observation 1 year after accident, with active aneurysmal signs, and was discharged unimproved.   |
| Notable swelling of arm, difficult deglutition.                                  | Rest, diet, wet compresses (arnica), ice-bags.                          | None.   |  | Wound healed and patient took his first promenade on 21st day; after this no history can be obtained.  |
|  | Compresses perchlorid of iron and glycerin, pressure, opium, ice, rest. | Three weeks after injury operation attempted, but patient succumbed at first incision.  | Pain in shoulder and elbow.  | External wound had healed already when first secondary hemorrhage occurred. Autopsy revealed arterio-venous nature of injury.  |
| Arm paralyzed, anesthesia of fingers, skin cyanosed.                             | Instrumental compression; not improved.                                 | None.   | Partial paralysis fourth and fifth fingers.  | Came under observation 2½ months after injury and was discharged unimproved in any respect.  |
| Swollen, cold, purple, pulseless, medius, ring, and little fingers paralyzed.    | Compression; bandages to arm.   | None.   | Edema of arm; varicose veins of arm.   | Ten years after operation patient was reported by friends in almost perfect health.  |
| Pulse weak and retarded, cyanosis, enlarged veins, etc.                          | Wound packed with iodoform gauze.                                       | On 9th day (midnight) clavicle resected; artery ligated on outer side of scalenus, subclavian and other veins ligated; wound allowed to heal by granulation.  | Arm cold and pulseless during operation; pulse did not return.   | Discharged a few weeks after operation healed; resumed occupation as a stone-cutter; no gangrene or disability of extremity reported.  |
| Pulse weaker.  | Antiseptic dressings to wounds.   | No operation.   | Arm feels numb; tingles when allowed to hang.  | 7 mos. after injury all signs of aneurysm persist, but suffers no inconvenience, and follows regular occupation (locksmith).   |
| After injury radial pulse retained.  | Antiseptic dressings.   | On 9th day artery ligated outside of scalenus; axillary artery ligated beyond wound; both axillary veins tied and venous branch from scapula ligated; clot turned out of sac and wound packed.  | Immediately after operation arm white and cold; veins thrombosed, arm blue and hand swollen; sensibility impaired; thermic sense lost; arm diminished in size. | Last report 8½ months after injury; marked disability of arm and hand; trophic and vascular changes marked.  |
| Pulse lost immediately, returned 5th day.  | Gauze compress and adhesive plaster, ice-bags.                          | On 9th day, Sept. 13, 1900, subclavian ligated on both sides of scalene; lateral suture of vein; osteoplastic resection of clavicle, provisional traction loop around anomalous subclavian first portion; wound healed per primam.    | Sloughing of thumb and little finger, part of hand and forearm.  | Last report July 1, 1901; patient in robust health; right hand and forearm permanently disabled.   |
| Arm motionless from fracture.  | Gelatin injection, immobilization bandage.                              | Operation for suppurating sac, Sept. 22, 1900; resection of clavicle; prophylactic ligature of subclavian artery impossible; free incision into sac; frightful hemorrhage controlled by 7 forceps left <i>in situ</i> ; wound packed. |  | Death four hours after operation from surgical anemia and shock. Autopsy: non-union of fracture; internal jugular and subclavian veins torn by distal fragment, subclavian artery perforated also; scalenus anticus torn from attachments. |
|  | Bandage for fracture.   | No operation attempted, patient too weak.   |  | Death five days after admission to hospital while en route to his home; aneurysmal hematoma enormous, filled entire supra-clavicular space front of chest and back, displacing scapula.  |

the patient survived the immediate effects of the injury and of the arterio-venous aneurysm that followed it for variable and often long periods of time. The study of these cases shows, however, that while the active persistence of the lesion is compatible with a long survival (ten years in two and as long as thirty-two years in one), they also show that in the vast majority—all but two—the lesion persisted in an active state in spite of sustained

efforts to cure it; in many, the final outcome could not be ascertained, but in others disastrous consequences followed in consequence of disturbances of the circulation in the extremity. All this shows that arterio-venous aneurysms of the subclavians, like those of other large trunks, persist as pathologic conditions, which are only tolerated by the organism, and remain a vulnerable point in the vascular system, which may lead—even after years

of toleration—to disaster and death. These facts alone would justify a more aggressive attitude toward this form of vascular lesion on the part of surgeons were it not that the dangers of the operation required to eradicate it are not to be underrated, even with all the advantages of the modern technique.

In conclusion, while recognizing that a decision in this matter must rest largely with the personal equation and experience of the operator, we believe that in all fully-established arterio-venous aneurysms which are well tolerated and give rise to little disturbance—and are presented by patients who can be kept under periodical observation—the old rule of non-intervention is still in order and should be followed. On the other hand, we believe, with Delbet, that with the improved conditions of the present day the indications for interference have broadened, and that whenever the lesion is not well tolerated, and gives rise to serious circulatory or other disturbance, it is justifiable to operate with the view of extirpating the lesion, especially when situated in the more accessible third and second divisions of the artery.

#### APPENDIX.

#### TWO ADDITIONAL CASES OF TRAUMATIC ARTERIO-VEINUS ANEURYSMS OF THE SUBCLAVIAN VESSELS, AND ONE OF INJURY OF BOTH VESSELS, NOT INCLUDED IN THE TEXT.

CASE I. *Arterio-venous aneurysm of the right subclavian artery and of the subclavian and internal jugular veins, caused by indirect fracture of the clavicle; operation; death.*—Operator, Dr. Vallas, Hôtel Dieu, Lyons. Reported by MM. Gallois and Piolet.<sup>1</sup>

A. F., aged 25; farmer; good antecedent history, but weak constitution; small stature and spare build; habitually pale. On July 2, 1900, while riding a mule the patient was suddenly thrown to the ground. He first fell on his feet, and then on his right shoulder. He felt an acute pain in the shoulder, but picked himself up and led the mule back to his stable. In doing this he had to walk up an inclined road by a hillside for twenty minutes. While on his way home he became conscious of the formation of a large swelling at the root of the neck on the right side. This swelling increased rapidly, and by the time he reached his house it had reached the ear and projected beyond it. As he walked he became short-winded, and when he arrived at the house he was completely exhausted. He could not stand on his feet, and had to go to bed at once. A physician who was summoned detected a fracture of the clavicle, with considerable subcutaneous emphysema. In the days that followed the swelling rapidly diminished, while a very considerable ecchymosis spread from the neck to the corresponding side of the chest.

When on the tenth day the bandages were removed a persistent but almost painless tumor had formed immediately above the clavicle and outside of the sternomas-

toid muscle. As this tumor remained the patient consulted other physicians at Grasse, who diagnosed an aneurysm of the subclavian artery, caused by fracture of the clavicle. On September 9—about sixty-two days after the accident—a gelatin serum injection, prepared by Lancerneau's method—was administered.

The patient was then advised to enter Professor Ollier's clinic at the Hôtel Dieu, Lyons, where he was admitted September 19. Condition on admission: The supraclavicular fossa is filled with a mass as large as a fist, which extends from the outer edge of the clavicular attachment of the sternomastoid to the outer third of the clavicle. The tumor is globular in shape, but irregular in contour. The upper outline of the tumor can be felt four fingers' breadth above the clavicle. It is most prominent about the level of the fracture, which is situated at the junction of the outer with the middle third of this bone. There is a complete failure of osseous union; the fragments are movable. The inner fragment projects under the skin anteriorly. The outer or acromial fragment is driven inward and backward, but appears to be outside the anterior scalene. The patient can scarcely move his arm, which hangs motionless by his chest. All the signs of aneurysm are recognizable in the tumor, except that there is no thrill. There is a distinct systolic murmur and expansile pulsation. Pulse, 100, can be distinctly felt at both wrists, though weaker on the right side. The right carotid can be outlined along the inner side of the sternomastoid. No pleural or pulmonary lesions. No apparent lesion of brachial plexus. A swelling still remains at the seat of the gelatin injection. On September 20 the patient complains of pain in the aneurysm. He has fever. Temperature, 38.8 C.; pulse, 108. The swelling, indicating seat of injection.

On September 21 the tumor increases rapidly in size; the overlying skin is red, edematous and inflamed. The seat of gelatin injection is also evidently inflamed and infected.

In the absence of Professor Ollier, Mr. Vallas takes charge of the case and diagnosticates "an inflamed aneurysmal hematoma, with threatened suppuration of the sac and general septic infection." It is decided that an operation is urgently indicated, and Mr. Vallas operates Sept. 22, 1900. Ether anesthesia. A horizontal incision is made parallel with and one finger's breadth above the clavicle; this is joined by a vertical incision following the inner edge of the sternomastoid down to the sternum. The insertion of the sternomastoid is divided and reflected upward together with the cutaneous flap. The omohyoid is divided in the middle, and each end is retracted. The sac is now exposed. In order to expose the subclavian, which is hidden by the tumor, the whole inner fragment from the line of fracture to the sternoclavicular joint is disarticulated and excised.

Notwithstanding the great exposure of the field obtained by this procedure, it is still difficult to recognize and isolate the subclavian artery. The trunk of this vessel is hidden by the sac and the large trunk of the right innominate vein. At this juncture, while exploring for the artery with a grooved director, a discharge of about a tablespoonful of thick, reddish pus takes place, and the director penetrates into the cavity of the sac. At the same time a large clot appears and obliterates the opening made in the sac. In view of the difficulty of applying a prophylactic ligature upon the subclavian artery at its origin, M. Vallas decided to make a large free opening into the sac, with the view of securing the injured and bleeding vessels *in situ*. The instant this is

<sup>1</sup> Revue de Chirurgie, Paris, July 10, 1901: 21me Année, pp. 23-30.

done a flood of mixed blood and clots deluges the field, the hemorrhage coming simultaneously from many points. In spite of a vigorous tamponade of the sac, the blood continues to flow. It appears to come most vigorously from the upper and inner angle of the wound. The cutaneous incision is quickly enlarged, and while the assistants are making vigorous compression at the bottom of the sac, the operator succeeds with much difficulty in placing two forceps on the internal jugular, one within and the other outside the sac. This stops the bleeding at this point. On removing the gauze packs the hemorrhage instantly recurs, pouring from several orifices. After great difficulties and much loss of blood, the bleeding is finally controlled by a series of forceps applied to the chief bleeding points.

In the meantime the patient grows very weak, and 500 grams of saline solution are injected and other restoratives are applied. The wound is packed with iodoform gauze, leaving seven clamps *in situ*. The patient is then put to bed, but in spite of the additional injection of 500 grams of saline solution death takes place four hours after the operation.

*Autopsy.*—A very oblique fracture of the clavicle is recognized, the sharp edge of the outer fragment projecting four centimeters beyond the line of fracture. The scalenus anticus is almost completely torn from its attachment to the first rib. The internal jugular vein is opened longitudinally by a tear two centimeters in length. The subclavian vein had been almost completely torn across, and its walls were incorporated in the sac.

The subclavian artery showed a small perforation which communicated with the sac. The tear in the artery had taken place a short distance from the thyroid axis. The internal jugular was also opened and freely communicated with the sac. The distal fragment had, therefore, been driven into the neck, tearing the scalenus anticus and penetrating the subclavian and internal jugular veins and the middle third of the subclavian artery.

**CASE II.** *Arterio-venous aneurysm—probably of the subclavian artery and vein—caused by indirect fracture of the clavicle; no operation; death.*—Service of D. Reboul, Montpellier, France. Originally reported by Th. Fabre,<sup>2</sup> and abstracted<sup>3</sup> from Gallois and Piollet's article, in the place quoted.

J. A., aged 30 years, locksmith, fell from a carriage March 4, 1894, and struck left shoulder. The clavicle was fractured at the junction of the outer and middle third. The fracture was set with immobilizing bandages. Eight days after the accident the patient removed the bandages and tried to use his arm. While moving the arm he felt a sharp pain at the seat of the fracture, which radiated to the dorsal surface of the forearm and hand. On March 31—nineteen days after this occurrence—another sharp pain was felt by the patient, and a tumor was noticed in the supraclavicular space on a level with the fracture. On April 8 the patient was seized with a violent cough, the swelling greatly increased in size, and became most painful. A traumatic aneurysm was then recognized by the attending physician. On April 10 he was seen by Dr. Reboul, who confirmed the diagnosis. All the signs of aneurysm existed, including a marked thrill and signs of venous disturbance. The tumor extends over the left thoracic region and covers an immense area. It extends five centimeters below the nipple, fills the axilla, and descends to the ninth rib; it projects posteriorly in the dorsal region, where it lifts

the scapula and displaces it outward, and can be felt transversely, touching the vertebral column downward to the tenth rib. The entire supraclavicular space is filled by the pulsating hematoma, up to the posterior border of the scalenus. The veins are turgid and obstructed. The left arm is powerless. Marked trophic disturbances exist in the arm, showing lesion of the brachial plexus. The pulse in the left brachial and radial arteries is scarcely perceptible. In addition to this great vascular disturbance, the patient gives evidence of advanced pulmonary tuberculosis and of chronic peritonitis. In view of all these complicating and hopeless conditions, and the very bad state of the patient, which would not even justify the administration of an anesthetic, Dr. Reboul decides not to interfere. Five days after his admission to the hospital the relatives of the patient decided to take him to his village. He died *en route*, and no postmortem was held.

Gallois and Piollet, after a careful consideration of this case, believe that it should be classified as an arterio-venous aneurysm, as all the signs pointed to a lesion of both artery and vein. In Gallois and Piollet's very interesting contribution, ten observations are summarized from the literature, which illustrate the dangers of closed—simple—fractures of the clavicle from the standpoint of complicating lesions of the subclavian vessels. In only two of these ten cases were both vessels—artery and vein—implicated, and these are so rare and instructive that they are worthy of the special and full mention given them in connection with the subject of this paper.

**CASE III.** *Subclavian artery and vein tied under the clavicle for hemorrhage in abscess cavity.*—Operated on in the surgical clinic of Prof. J. A. Yefremowski. Reported by M. A. Vasilyeff.<sup>4</sup>

M. L., female, aged 20, entered clinic Nov. 21, 1884. Patient first felt pain caused by an abscess (?) two weeks previously. Tumor was found in right axilla, which increased until the 29th, when it occupied the subclavian and axillary regions. December 1, under chloroform; incision made by Vasilyeff in axillary line, much pus issued; finger inserted in abscess cavity ascended to middle of clavicle; wound enlarged and drainage inserted; great hemorrhage occurred, stopped by grasping bleeding-points *en masse* with hemostatic forceps and left in place. December 3, dressing changed. Much bleeding at night. December 4, pulse, 104; temperature, 38.6 C. Professor Yefremowski, under chloroform, enlarged wound, sought cause of hemorrhage; on removal of forceps, hemorrhage great and subclavian artery was then tied; hemorrhage stopped a while, then began again, and was venous; subclavian vein was then tied. Wound was disinfected, packed and bandaged; patient put to bed; hot bottles around arm. Profuse sweating at night. Pulse in left hand, 100; temperature, 39.3 C. December 6th to 20th, daily change of dressing. Temperature varied, 38 C. morning to 39 C. night and more. Pulse in radial artery of operated arm not found; edema of arm in spite of flannel bandage with pressure. December 14, ligature slipped from artery. Small abscesses in little finger and palm: opened and dressings changed on alternate days; wound healed by granulation; edema; tumor in region of external middle third of humerus; acute osteomyelitis of humerus; two counter openings made and drains inserted inter-externally. March 1, erysipelas in the arm and chest; wound healed the middle of the month. Wound healed; function of arm limited; right arm thinner than the left. Movement in shoulder and elbow-joints impossible. Massage, active and passive movements. Electricity.

June 16. Left hospital. Movement in shoulder-joint; almost re-established in elbow; in phalangeal, metacarpal joints flexor movements imperfect; no pulse in right radial artery.

2. Thèse Montpellier, 1894.

3. *Revue de Chirurg.*, No. 7, July 10, 1901.

4. *Chir. Vestník*, 1886, II, pp. 431-436.

Patient was seen in the fall of 1885; improvement; does hard work; no radial pulse, right arm thinner than left

This case is properly not one of arterio-venous aneurysm of the subclavian vessels, but simply illustrates the dangers of hemorrhage and infection following a secondary ulceration of these vessels when exposed in a suppurating cavity. As this observation, originally published in a Russian journal, is difficult of access, it is here reproduced for the benefit of other students of the literature of the subject who may be interested in the nature of the case in consulting the bibliography.

## The Organization of the Medical Profession.

(Continued from page 351)

### IV.

#### Transferable Record of Professional Standing Necessary.

A system by which information may be had of those legally entitled to practice medicine is sadly needed. The ignorance regarding the number of physicians in a county or state is a reflection on the business sagacity of our profession, to say the least. There is hardly a state in which it is possible to make more than a fair guess as to the number of physicians it contains, and he would be bold, indeed, who would assert that he knew within 10,000 how many physicians, legally entitled to practice, there are in the United States. This uncertainty as to numbers is an evidence of ignorance as to other important facts relative to the profession taken individually and collectively. The other day an advertising quack in one of the western states, a graduate of an "easy" medical school of Chicago, acknowledged paying \$1000 for the questions of the Board of Examiners before which he had to pass an examination, or leave the city in which he had in a short time secured a paying practice by the aid of a large amount of printer's ink. This crime would be a bar to this individual ever securing a license in another state if the facts followed him. At another place during the same week a physician was convicted of swindling one of his patients and sentenced to three months' imprisonment. When he has served his time, he will seek another field and succeed in getting a license elsewhere, because, except in a very few states, his antecedent professional and personal character will not be inquired into. These are not isolated instances. Our profession should purge itself of the dishonorable and criminal in its ranks as the legal profession disbars its criminal members. It is a duty it owes to itself as well as to the people. But to be able to do this it will be necessary that it have some method of keeping a record of its members no matter where they may be or how often they may move. This means a system of the registering of and keeping in touch with all who are legally entitled to practice, whether they are members of the regular organization or not. This may appear to many to be something that is impracticable, impossible and not necessary. But it is both practicable and possible, as shown by similar achievements in other spheres of action, and it is absolutely necessary if professional organization is to mean anything. A system of registration, as recommended by the Committee on Reorganization, which will be referred to later, gives the organization information about each individual legally en-

titled to practice, and his qualifications. It puts a label on each one. When all the states are organized, it will be a simple matter to follow each individual, no matter how often he may change his location. By a system of cards, members will be transferred from one county society to another without expense or trouble. Members of the organization who are anxious to be classed as reputable will not object or hesitate to transfer their membership when relocating. Others, for obvious reasons, will not co-operate but rather resist such registering or transferring of information regarding themselves. In such cases the information desired may be difficult to obtain, but it can and must be had no matter at what cost. Thus the record of each will be known no matter where he may be. As the Committee on Reorganization said in its report: "When a little thought is given to this proposition, it will not be found so difficult as at first might be supposed. The local registration of physicians, as provided by law in most of the states, will be a great assistance in keeping up such a system. A 'card index' method of identification of the legal practitioners of the United States is practical, of easy accomplishment, and will do more to put down quackery and expose pretenders than anything else that can be done. It gives an answer to the questions, 'Who is he?' 'Where is he from?' 'What are his qualifications?' 'What is his reputation?'"

#### Physicians' Directory.

Bearing on this interesting question another paragraph of the Committee's report must be quoted: "Another thing greatly needed is a reliable physician's directory or register. Business houses are publishing what are called medical directories, but without exception all are unreliable. The best of them contain the names of pretenders, patent-medicine vendors, horse doctors, *et id genus omne*.\* The qualifications may be given correctly, if the necessary information can be gotten easily, otherwise not. The profession in this, as in many other ways, is used by commercial houses as a means for money-making, and if there is money in publishing a directory, and there most certainly is, the profession should have it and at the same time control it. . . . With such a system of registration as recommended, information necessary for issuing a directory will always be ready without extra expense; it will insure a reliable book and one that will mean something. It will not be necessary to go outside of the profession for anything. The printing establishment now owned by The American Medical Association, with a little addition, can get out the book. State directories can be printed, and the same material, without any change, can be used in making the national directory. There will be no duplication of work. The national directories can be issued bi- or tri-ennially, and a supplement annually, and also the state, when called for, separately and annually. The matter when once set up can be left standing, and corrections made as necessary. The Committee believes that the publication of official, reliable directories, state and national, is worthy of earnest consideration on the part of every physician."

\*An exception might here be made of the excellent "Directory of New York, New Jersey and Connecticut," published by the New York State Medical Association. Even this, however, on account of the lack of the proper machinery of organization hitherto existing, has its imperfections, while nearly approaching the desideratum than anything else of its kind existing.

It would be superfluous to take space to further consider reasons for organization. What we have already said has been simply repeating what every physician who has given thought to the subject has long since known. It must be emphasized, however, that the idea of a medical society being a scientific organization for educational purposes only must be abandoned. The times and the existing social and political conditions demand not only a different system of organization than has prevailed, but also recognition of broader views regarding the functions of medical societies, if the integrity and honor of the profession are to be upheld. The haphazard, loose, unsystematic and antagonizing methods that have been prevailing must give way to business-like organization and a systematic co-ordination and centralization of all the bodies into one.

#### Importance of County Societies.

Keeping in mind the objects of organization, it will readily be appreciated that the county society is the most important of all the medical bodies. While the state and national societies are necessary, their greatest value depends on the fact that in them can be centered the power and influence of the county society, and that through them the county society can be created, supported, encouraged, and made most useful to its members, both for educational and general purposes. Without the sacrifice of time or money in reaching its place of meeting, the county society<sup>1</sup> furnishes to every physician the opportunity of membership with the professional, social and material stimulus belonging thereto; it produces harmony, promotes good fellowship, removes petty jealousies, has an elevating influence on its members, and aids them in educational and scientific advancement. It is through the county society that the individual must be reached and given the opportunity to register his views regarding the measures and questions which affect him and consequently the profession as a whole. Through it must be reached those who are apathetic, indifferent and ignorant of the value of medical associations. Political influence depends on the machinery of which the county society is the all-important part, for only with its aid can we reach and influence the legislator at his home and among his supporters, and consequently where influence will have the best effect. The enforcement of medical laws, the eradication of quackery, which prevails both in and out of the profession, can not be thoroughly accomplished except by the aid of a live county society; collective investigation depends on it to reach out to the individual practitioner for his part of the great work of centralizing medical knowledge. Only through it can be had a record of those legally entitled to practice, including their qualifications, standing, etc.

#### Why Organization has Failed in the Past.

Bearing this in mind, those who have given thought to the subject and have studied it in all its bearings, have long realized that a system of organization, to be successful and permanent, must have as its basis and unit the county society; that the county societies united

together must make the state society, and that the state societies united together must make the National Society, or the AMERICAN MEDICAL ASSOCIATION. But there must be a unity in this trinity and a trinity in the unity, each dependent on the other, but all making one complete organization.

(To be continued.)

#### The Medical Society—A Humble Suggestion.

DETROIT, MICH., Jan. 27, 1902.

To the Editor:—In the beginning, combinations of loyal and sympathetic brother physicians were formed for the single purpose of furnishing to suffering humanity the highest and best results of their united efforts. A miserable and contemptible minority recognizing the fact that all honest scientific avenues to fame and fortune were effectually barred against them, sad to say, hesitated not to avail themselves of this means of infamous and unethical public advertising for their own selfish purposes, prostituting the medical society in the identical interest which the medical society *ab initio* was intended to oppose and condemn.

The medical society, local, state, national or international, stands for much that is lovely and of good report. It would surely be unkind and ungrateful on my part to utter any word of reflection against the time-honored and beneficent institution the "Medical Society." Nevertheless, impelled by a sense of duty to all concerned, I offer the following suggestion as to a mild but in my opinion really important method of reformation in the manner of conducting medical meetings:

Instead of laboriously working up a program on the venerable stereotyped pattern, eliciting stilted and wearisome declamations from inexperienced and injudicious plagiarists, let us in preference have straight, genuine original work plus equally genuine professional intimacy and friendship. For example, when the annual meeting of our State Medical Society occurs let it be understood and duly appreciated that the chief aim and object of the meeting is Goodfellowship, and sweet communion and reunion among men who are in the best and truest sense of the term Brothers. Never for one moment overlooking or ignoring the central and essential proviso that any brother who is fortunate enough to be able to bring with him a real "message," a wise "word of counsel," a "new observation"; a "something," "anything" true and vital to contribute to the pre-existing sum of our knowledge and experience, will have a generous and appreciative audience and an inspiring opportunity to do himself and his *idea* full and ample justice. According to this plan the energetic and loyal secretary would be relieved of the painful duty of drumming up papers from all sorts of sources likely and unlikely, and the members of the agony of listening to papers plagiarized from all sorts of sources likely and unlikely.

Good warm fellowship and rational unlabored intercourse between "brethren in arms and rivals in renown," is surely the great desideratum in this rapid and mercenary age, and that secured, every other good and gracious result must inevitably follow.

The present régime might be fairly and justly illustrated by supposing a literary or social club through its secretary appealing to its members to be present on a certain day and at a certain hour; and imploring each individual member, male or female, to bring along and recite an original poem. Good medical papers are about as rare as good original poems, while wretched medical so-called "papers" are quite as painful to listen to as plagiarized idiotic poetry.

The system of the prearranged symposium on definite subjects carefully selected by the medical society and its friends seems to be a very attractive method and for one I most heartily approve of it. In conclusion, permit me to say that in all loyalty and good faith I humbly submit my suggestion to the readers of THE JOURNAL and the profession at large.

DONALD MACLEAN, M.D.

1. The necessity for district, in place of county, societies in certain thinly settled territory is recognized, and will be considered later. That district societies, made up of a definite number of county societies, will be valuable is also appreciated.

## GRANULAR DEGENERATION OF RED BLOOD CELLS

The so-called granular degeneration of the red blood corpuscles of Grawitz has been a subject for much discussion. It is characterized by the presence in the red blood corpuscles of basophilic granules. Some investigators consider the bodies to be fragments of broken-down nuclei (karyorhexis), others believe them to be artefacts or postmortem phenomena, while most authors agree with Grawitz in recognizing the basophilic granules, sometimes seen in red blood corpuscles, as due to degenerative changes in the cells, and having no connection with a process of karyolysis. This form of degeneration has been observed in a variety of diseased conditions, such as pernicious anemia, malaria, carcinoma of the stomach, various suppurative diseases, leukemia, lead poisoning, etc. It is especially prominent in cases of poisoning by lead, and may be found in the blood of persons working with lead when all other signs of poisoning by the metal are wanting. Moritz succeeded in producing the basophilic granules in rabbits by feeding them pills of acetate of lead and, like Hamel, he found typical basophilic granules in the erythrocytes in six employees of a lead factory, in only one of whom were any of the usual symptoms of lead poisoning to be elicited. The granular degeneration of the red blood corpuscles was not found by Grawitz in healthy persons, nor in those with tuberculosis, chlorosis, diabetes, measles and pseudo-leukemic anemia.

The latest contribution of Grawitz<sup>1</sup> bearing upon this subject appears to contain some facts with important practical significance. In the comparative examination of the blood of patients with various diseases, he found that the blood of those who suffered from hemorrhage into the intestinal tract, especially those with gastric ulcer, carcinoma of the stomach, and also with intestinal hemorrhage following cirrhosis of the liver, exhibited granular degeneration of the red blood corpuscles in a striking manner, which was not present previous to the hemorrhage and disappeared soon after its cessation. On one occasion he observed this phenomenon in a patient with pulmonary hemorrhage where considerable blood was swallowed. After external hemorrhage the granular degeneration was absent. Such observations led Grawitz to suspect that the blood in the digestive tract gave origin to poisonous substances which were absorbed and affected the nutrition of the

red blood cells. To prove this he selected persons who had no changes of the blood and no severe organic diseases and exhibited to them some of the various preparations of hemoglobin which have recently been so much advocated as substitutes for the various preparations of iron. He found in persons, especially females who were already moderately anemic, that granular cells appeared in the promptest manner and with the smallest doses, while in robust men larger doses were required, and in many no effect was obtained.

These observations appear to prove the truth of the conjecture that during the passage of blood or blood preparations through the digestive canal of man, substances are formed which exert an influence upon the nutrition of the plasma of the red blood cells in the circulating blood. It may be that the elaboration of these poisonous substances is accomplished by the action upon the blood of the putrefactive bacteria of the intestine. These observations throw an interesting light upon the occurrence of blood degenerations from auto-intoxication from the intestines, and especially upon the question of the origin of ancylostomum anemia. In the latter case it is probable that the anemia following ancylostomum infection may be in part due to absorption of toxic substances, which have no connection with the worms as such, but are elaborated from the blood constantly poured into the intestinal lumen. If further investigations substantiate the correctness of Grawitz's observations and his deductions from the same, the numerous blood-making agents which have been so highly praised must be looked upon with suspicion. If they indirectly induce degenerative changes in the blood cells, their lauded advantages over the older preparations of iron becomes very doubtful at least.

## DIPHThERIA BACILLI AND NOMA.

It has been known for a long time that noma occurs in persons, especially children, when the general resistance of the body tissues has been lowered by various diseases, more especially by measles, but also by pertussis, scarlatina, typhoid and typhus fevers, and in one case, reported by Le Count, by amebic dysentery. Writers have generally suspected that some "specific agent" acts upon such susceptible tissues to produce the gangrene, and various investigators have described bacteria which they believed to be the essential cause of the necrosis, but subsequent research has failed to demonstrate the constant presence of any one of these microorganisms.

In October, 1895, Bishop and Ryan<sup>1</sup> reported before the Chicago Pathological Society a case of noma and two cases of ulcerative stomatitis, all occurring in brothers who had recently recovered from measles. From the case of noma and from one of the cases of ulcerative stomatitis, cultures of bacilli were obtained which cor-

1. Transactions of Chicago Pathological Society, 1894-95, I, 252-264. THE JOURNAL A. M. A., 1895, xiv, 1043-1046.

responded culturally and morphologically to the diphtheria bacillus, but which possessed only a low degree of virulence for guinea-pigs. In stained sections of the tissues from the case of noma, the same bacteria were found in abundance at the line of advancing necrosis. In the other case of ulcerative stomatitis the cultures are of little interest, as they were made after prolonged application of antiseptics. In view of the reduced virulence of bacteria isolated, Bishop and Ryan hesitated to state positively that they were true diphtheria bacilli. In 1896 Nicolaysen examined two cases of noma bacteriologically and found in each a bacillus resembling the diphtheria bacillus, but not pathogenic for experimental animals. In 1898 Freymuth and Petruschky reported two cases of noma in which diphtheria bacilli were found and in both of which diphtheria antitoxin was used with favorable results. They call attention to the reduced virulence of the bacilli. In view of the subsequent studies, it is quite probable that the organisms of Bishop and Ryan and of Nicholaysen were true diphtheria bacilli. Recently Walsh<sup>2</sup> reported the finding of diphtheria bacilli in eight cases of noma. Sailer<sup>3</sup> has just published two cases of noma, complicating typhoid fever. In the necrotic and gangrenous areas of both cases the diphtheria bacillus was found by cultural examinations. Sailer says that the first article in which attention was called to the possibility that noma, in some cases at least, is due to the diphtheria bacillus was that of Freymuth and Petruschky. This is certainly an error, as Bishop and Ryan clearly discussed such a possibility and were evidently strongly of the opinion that the organism described by them was the diphtheria bacillus with reduced virulence. The credit, therefore, of first calling attention to such a possibility is clearly due to the American observers.

Sufficient evidence is now at hand to show the close relationship between some cases of noma and the diphtheria bacillus, and to demonstrate the value of the diphtheria antitoxin as a therapeutic measure in such cases. In all cases of noma, as in other forms of probable infection by diphtheria bacilli, the administration of diphtheria antitoxin, until a bacteriologic examination can be made, is strongly indicated. Prophylactic measures should also be carried out.

#### PHYSICIANS AND DENTISTS.

The intimate relation of the condition of the teeth to the general health is becoming more and more recognized. After middle life many digestive disturbances are intimately associated with poor teeth. He who treats a patient for digestive derangement without first ascertaining the condition of the teeth neglects not only an important aid to the recognition of the cause of the condition in many cases, but also fails to find one of the most significant indications for treatment. Hunter's

articles<sup>1</sup> and his book on "Pernicious Anemia" have called special attention to this subject. There seems no reason to doubt that carious teeth may not infrequently be the source of serious gastric disturbance and even eventually of the anadenia of the stomach that is associated so often with pernicious anemia. Caries of the teeth in these cases may not be of the kind that produces serious discomfort. It is the latent painless foci of decay that especially prove niduses for bacterial growth and so flood the gastro-intestinal tract with septic micro-organisms that can not but prove harmful.

Of late we have come to realize that the mouth may prove a source of many infections. In present-day medical thought, acute rheumatism is believed to be of infectious origin. The portal of entry in many cases is undoubtedly the tonsils. The presence of other micro-organisms in the mouth, fostered as they are by carious teeth, is believed by many to be the cause for the change in the mouth secretions that encourage the multiplication of the bacilli whose entrance into the circulation sets up the joint symptoms. Mild forms of endocarditis and pericarditis, spoken of as rheumatic, for want of a better name, though they are associated with no joint symptoms, not infrequently owe their production to infection from the mouth. These conditions are often spoken of as idiopathic because no definite lesion of origin can be traced. In many of them, however, oral septic conditions are the direct cause. Obscure cases of so-called malignant endocarditis may have their origin in the mouth.

Unclean dental instruments may very readily be the occasion for the introduction of many forms of virulent bacilli into the tissues. Dr. Willy Meyer recently called attention to the fact that osteomyelitis may be traced to infection after careless dental manipulations. It is manifest then that we must not only be careful of the condition of patients' teeth, but must be assured that dental treatment is carried on with due attention to modern surgical methods. Dentists are surgeons in the fullest sense of the word, with all a surgeon's responsibilities. It is perfectly easy for them to point to many patients operated upon without the niceties of asepsis who yet suffered no inconvenience from the neglect. Susceptible individuals will surely be affected. Delicate persons, rapidly-growing children, anemic adolescents and convalescents from prolonged illness, are especially liable to suffer from such neglect. It is these that the physician has oftenest to direct to a dentist's care. He must in every case assure himself that his patient is to be subjected to no additional risks because of dental professional neglect. The physician and dentist should have closer relationship than prevails at present.

PROF. EMIL SCHEFFER.

In the obituary column will be found the announcement of the death of Prof. Emil Scheffer of Louisville.

2. Proceedings of the Philadelphia Pathological Society, June, 1901, 179.

3. American Journal of the Medical Sciences, 1902, cxxiii, 59-67.

1. The Lancet, Jan. 27, 1900, et seq.

He was a chemist, well known for his researches to obtain a purified pepsin. Previous to his investigations nearly all the pepsin used in America was obtained in a crude form from Europe. Scheffer noticed that such salts as sodium and magnesium sulphates and sodium chlorid precipitated pepsin. Following this observation, he devised the following process: The mucous membrane of the pig's stomach, dissected off and minced, was macerated in acidulated water during several days. The liquid was strained, clarified and mixed with sodium chlorid. The floating pepsin was skimmed and dried and sugar of milk added to make a saccharated pepsin capable of dissolving twelve times its amount of coagulated pepsin. His purified pepsin was made by redissolving the pepsin in water acidulated by HCl and precipitating, etc.: "a half-grain of this dissolved 1500 grains<sup>1</sup> of albumen." As the result of Professor Scheffer's investigations, pepsin is now manufactured in the United States in large quantities.

#### SCHOOLS OF MEDICINE.

Common talk about "schools of medicine" is too often allowed to go unchallenged because we do not emphasize the fundamental standpoint of scientific medical work. "Regular" physicians belong to no "school of medicine;" they are thus differentiated from those who hold certain tenets. That they are not "allopaths," that, in fact, there is no allopathic school, needs perennially to be insisted on. Allopathy or heteropathy, vide Webster, are synonyms invented by Samuel Hahnemann to designate a scheme of treatment which produces symptoms opposite to those from which the patient suffers. If such a rule of practice ever flourished, it has long since fallen into disuse. The teachings in the "regular" medical schools include no *à priori* generalizations about the causes of disease or actions of remedies. Teaching and practice are based, not on preconceived or inherited ideas, but on the logical principle of induction—first the gathering of facts enough to probably eliminate error, and then the drawing of conclusions from these facts. The method has been the same for all great investigators of nature, Bacon being its first exponent. Scientists whose work is firmly established on careful thinking and adequate results are often indifferent to lack of appreciation and misunderstanding outside of their immediate circle. They make little attempt to educate the public to any conception of the value of the best scientific efforts. The result of such neglect by medical men is apparent to the practitioner. He finds that the opinion and patronage of even the intelligent public are far more influenced proportionately by what this or that well-organized and skilfully advertised "school of medicine" has to say, than by all the painstaking research which has built up modern scientific medicine.

#### MEDICAL CLUB PRACTICE.

The evil of club practice that is beginning to be felt in some places in this country is a matter that the laity as well as the profession would do well to consider. No class of service can be obtained forever for less than its

real value; as the old darkey preacher said, apologizing for his small remuneration, if it was poor pay it was also "mighty poor preach." With the general disapprobation of the medical profession towards the practice it is not likely that many really able and competent physicians will take up with it for any length of time, and it is a sure rule that overwork and poor pay will not breed conscientious and skilful practitioners. There is, moreover, no inspection of or control over the product of a "sweated" doctor; the one who avails himself of his dubious services will have to take his chances, and these may, more often than he thinks, be rather slim as regards any real benefit in a serious case. It is not the improvident poor but the moderately thrifty individual who wishes to get something for his money that patronizes club doctors, and is "sold" through his ignorance or neglect of the very obvious moral and economic law that everything of real worth commands its price. Under the ordinary conditions of competition it is in the interest of the physician to do his best. Under the club practice the reverse is the case, and we do not claim that medical men who would knowingly engage in it are such self-denying saints as to neglect their obvious interest for the good of their swindling proprietors. These facts are well brought out in the report of a special commissioner of the London *Lancet* in its issue of January 4. It will be a good thing to impress upon the laity these aspects of the case; they evidently need some instruction in this special line of social economics. The evils to the profession, its degradation, etc., by club practice are self-evident to its members, but we have not been always altruistic enough to be sufficiently impressed by the evils to its supposed beneficiaries.

#### HEALTH OF HAVANA.

The December report of the sanitary authorities of Havana shows that that city had for the month a mortality ratio of only 20.47, which places it among the fairly healthy cities of its population and in an exceptionally favorable grade for a city in the tropics. What is still more significant, however, is the fact that yellow fever has for three months contributed nothing whatever to its mortality. Only three non-fatal cases were reported in October, and none at all since. The average mortality from this cause for the years preceding for which reliable records exist, 1871-1900, gives an average of about 30 annual deaths from this cause in December; in 1899 and 1900, with every attention to sanitation according to the then prevalent ideas of care as to infection, isolation, disinfection or destruction of fomites, etc., yellow fever was fully as prevalent in December as in the average of preceding years, excluding only the exceptional December of 1896. Only during the past year has any attention been given to mosquitoes as a cause, while at the same time the precautions as regards fomites were entirely laid aside, and the result is that the city has been free from the fever for the first time in a century. Taking the yellow fever year as beginning April 1, and comparing the last eleven years, the minimum number of deaths for the nine months, April to December, was 101 in 1899, the maximum 1262 in 1896, the mean 440. In 1901 under the new methods of prevention the deaths for this period

<sup>1</sup> U. S. Dispensatory, 18th Edition, p. 1013.

numbered only five. If there is any experimental proof that, so far as it goes, could be more convincing, we have not been able to imagine it. Considering the practical difficulties in exterminating the mosquito, the success is most remarkable and encouraging for future work in this direction. The report shows what can be done by efficient sanitation under most unfavorable conditions.

#### OSTEOPATHY IN NEW YORK.

The "osteopathy" bill before the New York Legislature is a fine sample of special legislation. It proposes to give to these masseurs all the rights and functions of medical practitioners to treat all kinds of diseases, sign death certificates, etc., without any state examination whatever. All that it requires is that they shall be members of the Osteopathic Society and payment of a fee of ten dollars. It is some comfort to know that the medical profession in the state is alive to the situation and is not slumbering over it. It is also satisfactory and encouraging to know that the lay press duly appreciates the conditions. The great New York dailies, the *Tribune*, the *Sun*, and the *Times*, speak in no doubtful tones and show that the intelligent among the laity are with us. The New York *Times* suggests the *reductio ad absurdum* by the proposition that some sensible assemblyman introduce a bill making it legal for any adult male citizen to sit in the chamber and legislate for the people. The little formality of an election is as unreasonable as demanding any examination into the qualifications of a would-be doctor, and it thinks the opportunity to demonstrate this at Albany is too good to be lost. The fact that the osteopaths have received a partial recognition or an exemption from the provisions of state practice laws in some states is an unfortunate one, but it will not be any excuse for the proposed New York legislation which proposes to put them at once on the same plane as all other practitioners without the wholesome safeguards that are demanded of the latter. Its presentation is an insult and its passage would be a wrong to every one who has duly qualified himself by study and expense and proven his competency under the existing laws. If osteopaths are to be permitted to practically nullify the New York medical practice acts what are we to look for elsewhere? If this bill should go through and receive the signature of the Governor, then farewell to any pre-eminence New York can claim for its medical standards.

#### DIVISION OF THE FEE.

The giving and taking of commissions has been repeatedly decried and the consensus of opinion among honorable men is that, unlike charity which "blesses him who gives and him who takes," it debauches both. That the practice is growing there can be no doubt. The peddling of cases from surgeon to surgeon by "drummer-physicians" who make a trade of their profession, caring less for the ability of the operator than for the percentage he gives, is ordinarily dwelt upon at length. It is clear, however, that the consultant surgeon or specialist who gives such a commission is equally culpable. He defrauds the patient, places himself in the power of

the case-vendor, and does himself a great injustice. He defrauds the patient by charging him for something he does not give. The surgeon is called to the case in question because of his supposed superior knowledge and operative ability. For the exercise of this knowledge and ability he has a right to command a fair price, but anything added to this, for the "drummer," is nothing more nor less than obtaining money under false pretenses. He puts himself in the power of the case-vendor the moment he bribes this individual to send him a case. Bribe-givers and bribe-takers are equally guilty in criminal courts, and they are equally despicable according to the code of ethics which governs the actions of all honest practitioners. The bribe-taker may at any time, either by intention or indiscretion, bring justly merited disgrace upon the unprincipled operator. No self-respecting surgeon can afford to hazard his reputation in the hands of such a bartering auctioneer. The percentage demanded by the case-vendor can be gradually increased, and the operator, having taken the first wrong step, must compete with other men as dishonest as himself. The injustice done the operator is a justly merited punishment, since he allows a third party to receive pay for the exercise of his own ability. The essential wrong, however, is that the patient is defrauded. As we stated some time ago,<sup>1</sup> the question simply resolves itself into this: Does the patient know of the transaction? If so, then it is legitimate and ethical; if not, it is collusion.

#### INDICATIONS FOR OPERATIVE TREATMENT OF DIPHTHERIC STENOSIS OF THE LARYNX.

Although the employment of antitoxin in the treatment of diphtheria has reduced not only the mortality from the disease but also the frequency of stenosis of the larynx and of the necessity of its relief by operative measures, cases do occasionally occur in which the obstruction to breathing is so pronounced as to render such measures imperative. In these cases also the good effects of serum therapy have been manifest. As between intubation and tracheotomy in cases in which operative intervention is required, it may be said that the former has steadily grown in favor, and its advantages, when it is indicated, are so obvious as to require no recapitulation here. On the other hand, conditions are sometimes present that render intubation impracticable or inadmissible, or at least render tracheotomy preferable, and it is therefore desirable to have and to keep clearly in mind the factors that determine the choice in favor of one or the other of these operations. This subject has received consideration in a study by Drs. George Alsberg and Sigmund Heimann<sup>2</sup> of the cases of diphtheria, to the number of 4033, observed at the Kaiser- und Kaiserin-Friedrich Kinderkrankenhaus in Berlin for the ten years from 1891 to 1900. As a result of this analysis it is concluded that operative intervention in cases of stenosis of the larynx of slight and moderate degree should be obviated so far as possible by means of antitoxin and the employment of sprays. Primary intubation is indicated in all cases of stenosis of the larynx of severe degree, in which, so

1. JOURNAL A. M. A., Feb. 2, 1901, p. 326.

2. Archiv für Kinderheilkunde, 33 B., II. 1, 2, p. 98.

far as the clinical picture makes it appear possible, a cutting operation can be avoided. Primary tracheotomy is indicated in the presence of asphyxia and collapse, of pneumonia, of severe heart disease, of paralysis of the palate and diaphragm of profound anatomic changes in the pharynx, as well as marked tumefaction of the entire pharyngeal structures when necrotic. Secondary tracheotomy is indicated when the symptoms of stenosis persist in marked degree with the tube in place, providing its lumen is not occluded, when pneumonia supervenes, and when paralysis of the palate and diaphragm supervenes. Intubation is not to be recommended in the case of nursing infants, on account of the diminutiveness of the parts and of the narrow lumen of the pharynx, but especially on account of the increased difficulty in feeding from the presence of the tube and which at this time of life is of vital importance.

## Medical News.

### ALABAMA.

**Birmingham Hospital.**—The Hillman Hospital Association is about to erect a hospital in Birmingham, to take the place of the temporary hospital now in use.

**Health Board Election.**—At a meeting of the Birmingham Committee of Health, January 15, Dr. Edward H. Sholl, was re-elected president and Dr. Dyer F. Talley, secretary.

**New Hospital for Montgomery.**—The Sisters of Charity have purchased a site for their new hospital in Montgomery at a cost of \$23,000. On this site they will erect a building to cost not less than \$50,000.

**Osteopathy in Alabama.**—Judge Samuel E. Greene, of the Criminal Court, has decided that osteopathy is the practice of medicine, and any person engaged in the same in Alabama can be forced to procure a license for practicing medicine. His decision was based on the definition of the word "medicine," which is, "science, which relates to the cure, prevention or alleviation of disease." The defendant claimed that osteopathy was not the practice of medicine, as no drugs were used.

### CALIFORNIA.

**Scarlet fever** is prevalent in East Oakland, Orville, and Oakland. The schools in Oakland are closed. In December 56 cases were reported and 30 cases during the first week in January.

**Los Angeles Emergency Hospital.**—The contract for this hospital has been let and by its terms the building must be completed in every particular within one hundred days. The building will accommodate 150 patients.

**Stockton Board of Health.**—At the meeting of this body for organization, January 13, Dr. Charles R. Harry was elected president; Dr. Samuel E. Latta, vice president, and Dr. Sylvester B. Davis, city health officer, and secretary.

**Sacred Heart Hospital, Oakland.**—The Sisters of the Sacred Heart, Oakland, have determined to erect a hospital on property owned by them and adjoining the proposed Oakland Medical College. The first building is to cost about \$50,000.

**Telephones and Disease.**—The Board of Health of San Francisco passed resolutions at its meeting, January 15, declaring that a very potent agent in the dissemination of disease is to be found in telephones, particularly those in public use, and requesting all inventors and manufacturers of appliances with germicide properties for attachment to telephones to forward working models of the same for examination to the board within the next sixty days.

### COLORADO.

**County Physician's Report.**—The physician of Arapahoe County reports that during 1901 he made 2221 calls and saw 6634 office patients, gave 345 prescriptions and furnished medicine in 7492 instances. There were 865 individuals admitted to the county hospital and 60 to the poor farm.

**Consumptive Home.**—Charles L. Adams has given \$50,000 to build an annex to the consumptive home in Denver, in memory of his deceased wife and to be known as the Mrs.

Charles L. Adams annex. Accommodations will be furnished to consumptives of moderate means for \$6 a week.

**Directors versus Men.**—The directors of the Grant Smelter, Denver, insist that Drs. Lewis E. Lemen and Hugh L. Taylor shall treat the employees. The men, who pay a dollar a month each for medical and surgical care, demand that Dr. Benjamin F. Wooding be exclusively employed. The labor commissioner has now asked the attorney general to decide who has the right to select the surgeons of a company, the men who contribute monthly from their pay, or the company itself.

**The Honored Dead.**—The deaths on the same day of Drs. Clayton Parkhill and J. T. Eskridge caused profound grief in Denver. The medical staff of St. Luke's Hospital passed resolutions of sorrow. The Arapahoe County Medical Society, at a special meeting, decided to set apart its next meeting as a memorial. The County Court adjourned in respect to the memory of the deceased, and the Chamber of Commerce adopted resolutions regarding the death of Dr. Eskridge. On account of his military services, Dr. Parkhill was buried with military honors.

### CONNECTICUT.

**Waterbury Hospital Bequest.**—By the will of the late Frederick A. Spencer of Waterbury \$10,000 is left to the Waterbury Hospital, subject to the life interest of a sister.

**Sand View Hospital Fire.**—A fire at Sand View Hospital, Stamford, January 8, caused much damage but fortunately was not attended by loss of life, as the patients were all removed in safety by the attendants.

**Doctor Wins Suit.**—Dr. Frank N. Loomis, Derby, who was sued for \$5000 by Martha A. Pope of Orange for damages alleged to have been received by reason of the defendant's carelessness in setting arm of plaintiff, has won the suit and will recover costs.

**Yale Appointments.**—In the current catalogue of Yale Medical School, New Haven, Dr. Frederick N. Sperry is noted as full demonstrator of anatomy; Dr. William S. Banes, as second assistant to the therapeutic clinic; Dr. W. H. Crowe, as clinical assistant in ophthalmology; Drs. F. H. Reilly and Thomas G. Sloan as assistants in the surgical clinic and Dr. Thomas C. Haines, as assistant in obstetrics.

**December Diseases and Deaths.**—The report of the State Board of Health shows that measles has slightly increased over the previous month. There were 36 cases reported from 16 towns. Scarlet fever prevailed in 48 towns, from which 260 cases were reported, with 18 deaths. Diphtheria and croup were unusually prevalent; 196 cases were reported with 43 deaths. A marked epidemic occurred in Stafford Springs and is still progressing. Typhoid fever is less prevalent than usual, but in New Haven the consequences of the epidemic of last April are still apparent, not die, however, to the infected water supply, but to neglect of perfect disinfection of the discharges from previous patients. One case of typhus fever was reported in Stonington. It is the only case of typhus in the state and the first one reported in several years. The total deaths for 1901 numbered 14,795, that being 1,545 less than in the preceding year. In March occurred the largest mortality, 1441; in June occurred the smallest number, 1022. The most fatal disease during the year was consumption, 1443. The next highest mortality was from pneumonia, 1382. Measles was fatal in the year to the number of 71. Scarlet fever caused 78 deaths. Diphtheria and croup killed 308. Typhoid fever mortality was 262. Whooping cough mortality was 92. There were only 3 deaths from smallpox.

### ILLINOIS.

**Scarlet fever** has caused the town of Arthur to be quarantined, its schools to be closed and public meetings prohibited. —Many cases exist in Florence Township, Stephenson County. —The disease still persists in Joliet owing to laxness of quarantine. —An epidemic is said to exist in Decatur.

**Hospital Dedicated at Lincoln.**—The new Deaconess Hospital at Lincoln was dedicated with fitting exercise January 19. The building is a three-story and basement structure, 108x85 feet. It contains 48 private rooms and four wards, in addition to the administration and operating rooms, and has cost about \$35,000.

### Chicago.

**Diphtheria and scarlet fever** are especially prevalent around the Harrison school at Wentworth avenue and Twenty-third place, and near Ogden and Turner avenues in Lawndale.

**Hospital Gets Interest.**—Mrs. Sarah A. Hawley has agreed, in consideration of an annuity of \$3000, to relinquish her right

to certain property valued at \$178,500 to the Chicago Orphan Asylum, Presbyterian Hospital and Newsboy and Bootblack's Association.

**The City's Insane.**—During 1901, the Detention Hospital received 1503 patients, who were distributed as follows: Cook County Asylum, Dunning, 667; Illinois Northern Hospital, Elgin, 203, and Illinois Eastern Hospital, 166. The remainder, about one-third, were discharged.

**Public Gynecological Clinics Stopped.**—Warden Healy, of the Cook County Hospital, on January 23, refused to permit an operation on a woman in the clinical amphitheater. He stated that he would not permit women who were patients of the hospital to be indecently exposed before medical classes.

**Chicago's Health.**—The Department of Health reports much disease, but of mild type. The 480 deaths from all causes recorded last week give an annual rate of only 13.73 per 1000 of population—a reduction of about 7 per cent. from the rate of the previous week, and of 3.8 per cent. from that of the corresponding week last year.

**Smallpox.**—Only eight new cases of smallpox were discovered during the week—two imported from Wisconsin and both sent to the health office in advanced eruptive stage; three were contracted from previous city cases and the origin of the remaining two is as yet unknown. Five had never been vaccinated at all, and the remaining three, aged 29, 30 and 50 years, respectively, had only imperfect traces of vaccination in childhood, never repeated.

### INDIANA.

**St. Mary's Infirmary.**—A new infirmary building to cost \$30,000 is being built for St. Mary's Academy, South Bend.

**Mishap to Physician.**—Dr. Oscar K. Guyer, Lewisville, while making a professional call, January 19, had a slight stroke of paralysis, fell from his buggy and broke his leg.

**Smallpox** has broken out in La Grange County, where three cases are reported.—On account of a case in the Indianapolis Foundry, the 400 employes of that establishment have been vaccinated. Indianapolis had 20 cases this year up to January 20.—Ten cases are reported in the western part of Howard County, where churches and schools have been closed.

### IOWA.

**Certificate Revoked.**—The State Medical Board has revoked the certificate of Dr. J. W. Crofford, Lamoni, who was recently convicted of the murder of Miss Maude Stone, and sentenced to the state penitentiary.

**Physician Fined for Breaking Quarantine.**—Dr. Samuel C. Kirby, Grand Junction, charged with breaking a smallpox quarantine last summer, was found guilty, January 16, and sentenced to pay costs of about \$400. He states that he will ask for a new trial.

**New Hospital for Cedar Rapids.**—Plans have been completed for a new hospital to be erected at Cedar Rapids by the Sisters of Mercy of the Church of the Immaculate Conception, to cost \$50,000. Abraham Slimmer has agreed to give an amount equal to that raised by the Sisters. They have already secured \$16,500.

**Hospital for Marshalltown.**—The Marshalltown hospital fund has received \$2000 from the estate of the late Bishop Lenihan; Father Lenihan, of Marshalltown, has added \$1000, and Archbishop Keane of Dubuque has pledged \$2000 additional. George F. Kirby, Marshalltown, has donated \$1000 to the fund. This makes a substantial start toward the \$20,000 required.

**Staff of Children's Home.**—The medical staff of the Iowa Children's Home, Des Moines, held its annual meeting, January 22, and elected Dr. James W. Cokenower, president and attending surgeon, and Dr. Lenna L. Meanes was re-elected secretary. The staff for the year is as follows: Drs. James W. Cokenower, William W. Pearson, Granville N. Ryan, P. J. Callahan, Charles F. Smith, Lenna L. Meanes, J. F. McKittrick and Clifton Scott.

### MARYLAND.

**Hospital Endowed.**—It is announced that a wealthy citizen of Hagerstown, who wishes to do good by stealth, has promised to contribute \$50,000 toward the endowment of a hospital in that city as soon as the plans have been formulated by the Washington County Medical and Chirurgical Association.

**New Officers Elected.**—The Maryland Hospital for Consumptives, Towson, at its annual meeting, elected Drs. Robert T. Wilson, George B. Reynolds and Henry B. Jacobs directors. The visiting staff consists of Drs. Henry B. Jacobs, G. Milton

Linthicum, Walter P. Smith, and Warren Buckler. Dr. Frank R. Rich is resident physician.

**Health Board for Baltimore County.**—A bill has been introduced in the legislature to provide for the appointment of a board of health for Baltimore County, to be composed of three reputable physicians, the state's attorney and the president of the Board of County Commissioners. The board's expenses are limited to \$2500 annually, and the board is empowered to select a secretary at \$900 a year.

### MICHIGAN.

**Hospital Opened.**—The Michigan Children's Home Hospital erected at St. Joseph, at a cost of \$7000, by Mrs. Chapin, of Niles, was formally opened, January 2.

**The oldest physician** in Grand Rapids, Dr. George K. Johnson, was given a luncheon, January 17, by his immediate professional associates, on the occasion of his 80th birthday. Dr. Johnson has practiced in the state since 1846, and in Grand Rapids since 1856.

**Detroit Clinical Laboratory.**—A laboratory has been incorporated in Detroit for chemical and bacteriological analysis and pathologic examinations for the treatment of disease, giving such instructions therein, and in hygiene, as may from time to time be necessary. The directors of the institution are Dr. Charles G. Jennings, president; Dr. William F. Metcalf, vice-president; Dr. Wadsworth Warren, secretary-treasurer, and Drs. Oscar Le Seure, Arthur D. Holmes, Frederick W. Mann and Ernest T. Tappey. The laboratory staff consists of Dr. Thaddeus Walker, superintendent of the laboratory and chief of the department of hematology and clinical analysis; Dr. Henneage Gibbs, chief of the department of bacteriology; Dr. Frank T. Stephenson, chief of the department of chemistry, and Dr. Preston M. Hickey, chief of the x-ray department.

**Recommendations for Medical Instruction.**—In the last report of the superintendent of public instruction he makes the following recommendations for medical colleges:

1. A standard of preliminary education should be required, and a board created to examine all students before entering upon the study of medicine.
2. Some safe, uniform standard for graduation ought to be fixed and insisted upon as a condition precedent to a license to practice medicine.
3. The financial solvency and stability of each institution should be more carefully guarded and insisted upon.
4. Medical colleges should not be chartered in small towns where clinical and hospital facilities, so necessary to the proper education of a physician, are not ordinarily found.
5. A constant and thorough visitation and inspection of such institutions should be regularly made by a board of visitors competent to fairly judge of their merits.
6. The capital of every medical college should be large enough to warrant the employment of men learned in their profession and the provision of equipment in all branches adequate to promise a proper medical course.

### NEBRASKA.

**Smallpox.**—In the first eleven days of the new year 49 cases of smallpox were discovered in Omaha.

**Scarlet fever** is epidemic in Clearwater, where the public schools have been closed and public gatherings suppressed.—Kearney reports five cases from as many foci of infection.

**Norfolk Hospital Deserted.**—Since the fire at the Norfolk hospital all the patients have been transferred to the state hospitals at Lincoln and Hastings, and the employes have been relieved from duty.

**Personal.**—Dr. Fred Rustin, Omaha, has been appointed surgeon-in-chief of the Presbyterian Hospital, vice Dr. Charles C. Allison, who has gone west in search of health.—Dr. A. H. Simonton, acting assistant surgeon, U. S. A., stationed at Fort Robinson, has asked for an annulment of his contract and will return to Alabama.—Dr. Walter H. Wood, Maywood, has gone to Europe for post-graduate study.

### NEW JERSEY.

**Diphtheria at Whitehouse** has caused the temporary closure of the public schools at that place.

**Hackettstown Epidemic.**—The old story of "Cuban itch," "Philippine measles," etc., seems to be responsible for the smallpox epidemic which cut off Hackettstown from the rest of the world. There have been 40 cases, but no deaths. At Allamutchy and Vienna four cases exist.

**Cooper Hospital, Camden.**—At the annual meeting of this institution the following were elected as members of the staff: Medicine, Drs. H. Genet Taylor, William A. Davis, E. L. B. Godfrey and William R. Powell; in surgery, Drs. Daniel Stroock, Joseph L. Nicholson, Paul M. Meccray and Edward A. Y. Schellenger; in ophthalmology, Dr. William R. Powell; in gynecology,

cology, Dr. Dowling Benjamin and Joseph S. Baer; in laryngology, Dr. Ernest S. Ramsdell, and in pathology, Dr. Walter S. Bray.

#### NEW MEXICO.

**Bazar for Hospital.**—The bazar recently held for the benefit of St. Joseph's Hospital, Albuquerque, which is being constructed by the Sisters of Charity of Cincinnati, Ohio, added more than \$2600 to the fund for the equipment of the institution.

**Dr. Judd Medical Director of the Montezuma.**—Dr. Norman W. Judd, for a long time on the editorial staff of *THE JOURNAL*, but who was obliged to go to New Mexico for his health, has been made medical director of the Montezuma at Las Vegas Hot Springs.

**To Enlarge Railway Hospital.**—The chief surgeon of the Santa Fe lines west, Dr. Norman H. Morrison, has let the contract for important additions to the company's hospital at Albuquerque, which, when completed, will make the hospital one of the largest on the entire system.

**For Consumptive Sailors.**—The Marine Hospital for Consumptives at Fort Stanton has now more than 100 patients. Six surgeons and about 100 attendants are on duty there. Hygiene, fresh air, regular habits and cleanliness are considered the cardinal points on which the possibility of cure depends.

#### NEW YORK.

**Careless distribution of medicines, drugs and chemicals** by leaving such exposed upon the ground, sidewalk, porch or doorway or in any other manner so that children may become possessed of same, is made a misdemeanor punishable by a fine of \$25, by a bill introduced by Assemblyman Richter.

**Postmortem Examiners.**—The State Civil Service Commission has decided that the physicians recently appointed post-mortem examiners, physician to jail and penitentiary are not entitled to be compensated because the positions are civil service positions and the physicians previously in office can not be removed except on charges.

**Vital Statistics.**—A bill has been introduced in the assembly to compel all local boards of health, except in counties wholly within a city of the first class, to file with the county clerk on or before the fifth of each month, a statement of each marriage, birth or death, with the date and place thereof, which occurred during the preceding calendar year in the city, town or village constituting its jurisdiction.

**New Lunacy Bill.**—Governor Odell's scheme to abolish the boards of managers of state hospitals for the insane, and substitute a visiting board for each district, to be appointed by the governor annually, has met with a storm of opposition. At the hearing in the senate chamber more than fifty charitable institutions in New York City alone were ably represented, and not one of these favored the bill.

**Bethel Prohibits Tuberculosis Sanatoria.**—The Board of Health of Bethel, Sullivan County, has adopted an ordinance prohibiting the maintenance, within the town limits, of public or private boarding houses or sanatoria for persons affected with tuberculosis, under a penalty of \$50 a week; also imposing a penalty of \$10 for the first offense and \$50 each week for entertaining a stranger or guest affected by tuberculosis other than immediate relatives or dependent on the family.

**Stony Wold Sanatorium.**—At the annual meeting of the incorporators of this sanatorium it was announced that the Lake Kushaqua property in the Adirondacks had been obtained for the sanatorium, and that ground would be broken for the buildings in the spring. This site is among the pines of Franklin County, at an elevation of 1730 feet. During the year \$48,000 have been raised, but the sum of \$60,000 will be required in addition in order to complete the building. The object of this sanatorium is to care for working women and children only who have incipient tuberculosis.

**State Hospital for Tuberculosis.**—The board of trustees of the State Consumption Hospital met at Albany. Howard Townsend was elected president and Dr. John H. Pryor, of Buffalo, secretary of the board. The officers of the board were authorized to purchase a site for the consumption hospital at Raybrook. Plans for the hospital buildings were examined, but final action was not taken. It is reported that the plans for building the hospital have met with a sudden set-back by the discovery that, according to the constitution of the state, trees on land bought by the state in the Adirondack Park can not be cut down. This prevents clearing the site recently selected for the hospital at Raybrook.

#### New York City.

**Another Decision in Favor of the Loomis Laboratory.**—Judge Patterson, in the appellate division of the supreme court, has handed down a decision, sustaining the action of the lower court in dismissing the claim of the New York University to the Loomis Laboratory. The litigation dates back to April, 1898.

**German Charity Ball.**—The twelfth annual German Charity Ball was held, January 23, under the auspices of the German-Americans, and it is thought that the net proceeds will reach \$10,000. This is to be divided among various charities, such as the German Hospital, St. Mark's Hospital, the German Poliklinik and St. Francis' Hospital.

**Street Refuse to be Used as Fertilizer.**—The new Street Cleaning Commissioner, Dr. Woodbury, has just made arrangements to have the Long Island Railroad take the street sweepings away in sacks and dispose of them to the farmers on Long Island. It is thought that a considerable saving will be thereby effected, and that in time this material may become a source of revenue.

**The Osteopathy Bill.**—Several medical organizations of this city have sent petitions, resolutions or personal representatives to Albany to actively oppose the osteopathy bill. The fight is to be on the ground that all classes of physicians, no matter what peculiar name they may adopt, should be equal in the eyes of the law, and that to grant special privileges to the osteopaths or to any other particular class will open the doors to quacks and make a farce of our medical laws. Senator Platt, in an interview, has undertaken the advocacy of the osteopathy bill. He quotes Senators Foraker and Cockerill as ardent osteopaths.

**A Costly Lying-In Hospital.**—The new lying-in hospital, built and equipped by Mr. J. Pierpont Morgan at a cost of \$1,350,000, is now ready to receive patients. It is eight stories in height, and possesses many new features both in construction and equipment. To facilitate cleanliness, angles are avoided, not only between the walls and floors, but even in the furniture. The wards are furnished in iron and glass, the floors are of fireproof sawdust, the curtains are hung outside of the windows, and excellent ventilation is said to be secured by a system of fans, which force filtered and warmed outside air into the wards and out again through pipes opening on the roof. Visitors are not allowed in the wards, but are accommodated in a reception room on each floor, and into this room may be wheeled the bed of any patient.

**The Smallpox Situation.**—The Board of Health has met with an unexpected obstacle in its efforts to fight the smallpox more effectively. It was supposed that as a large increase in the number of vaccinators was needed, it was only necessary to call upon the medical inspectors of the schools. It is true that the vaccinators receive a much larger salary, but they are required to be on duty from 10 a. m. to 4 p. m., and may be called on up to 10 o'clock at night. This alone would make many of the inspectors hesitate to accept the new position, but the fact that this increase in the vaccinating force is only temporary, and that the inspectors could not afterward return to their old positions in the schools, has led to a general refusal to join the vaccinating corps. This is a serious matter, for the disease is reported to be on the increase, and with the delay necessarily incident to the civil service restrictions it will be at least six weeks before new men can be obtained for the work.

**The City Milk Supply.**—The Rockefeller Institute has awakened a feverish interest in the milk supply of the city by a recently published report of its investigation. It declares that the great bulk of the milk coming to the city is far from pure, and backs up this statement with statistics gathered in connection with its research extending over a period of seven months. The report asserts that 330 outbreaks of epidemic diseases have been traced to milk. Of these, 195 were epidemics of typhoid fever, in 147 of which the disease prevailed at the dairy or farm. In 67 it was due to contamination of well water, and in 24 cases employees at the farms were acting as nurses, while in 10, although still sick, they were at work. There were 99 epidemics of scarlet fever, in 68 of which the source of infection was traced to the illness of persons at the dairy. In 17 instances, the employees were themselves suffering from scarlet fever, and in 10 they were acting as nurses to scarlet-fever patients. There were 36 epidemics of diphtheria, in 13 of which the disease existed at the farm or dairy. Continuing, the report says that more than one million and a half quarts of milk are delivered to New York a day, coming from five different states and forty-four counties, much of it being transported a distance

of 200 to 300 miles. It is asserted that in 1900 no less than 6055 infants in New York city died from the effects of impure milk.

**Exploitation of Tuberculosis Experiments.**—So much has been said in the lay press regarding the wonderful experiments made by a Dr. George D. Barney, and his alleged inoculation of Miss King with the disease from a tuberculous cow, that there is no occasion for medical journals to waste much space on the subject. It may perhaps be well to call attention to the final act in this desperate effort to gain notoriety, i. e., the obtaining from reputable physicians under false pretenses of certificates concerning the results of a physical examination of this Miss King, together with the heralding of the astounding news that she had not only been inoculated successfully with bovine tuberculosis, but that she had been actually cured of her tuberculosis in the course of a few weeks. Under an assumed name this woman called upon Dr. S. A. Knopf, and gave him a history, which would make it appear that the disease had only very recently developed. The disease was certainly in an early stage, but Dr. Knopf was inclined to think that it had existed longer than a few weeks. She secured a certificate from him on the plea that if she sent such a statement to her uncle in Colorado he might take her to his home. This was on December 5, and on December 9 she secured a certificate from Dr. Andrew H. Smith, also stating that the disease was in its incipency. On January 14, she was examined by Dr. Austin Flint, who declared that she was free from the disease. It should be noted that no evidence has been submitted to prove that this person was inoculated from the cow, while there is reason to believe that this woman was already suffering from pulmonary tuberculosis at the time of the alleged inoculation.

#### Buffalo.

The smallpox situation has improved perceptibly. Few cases are reported and they are only of a mild type.

**Personal.**—Dr. Walter D. Green, Health Commissioner, gave a dinner at the Genesee House for the members of his staff. —Drs. Beebie, Wright, McCarthy and Wheeler are acting temporarily as sanitary officers of the Health Department in the campaign against smallpox in the Polish districts. —Dr. Peter W. Van Pyma, who for the past four years has been chairman of the Board of School Examiners, has been reappointed a school examiner by Mayor Knight.

#### OHIO.

**Entire Board Expelled.**—To put an end to threatened scandal at the Dayton State Hospital for the Insane, Governor Nash wrote each member of the board of trustees, January 18, requesting his resignation at once.

**Hospital Needs Overhauling.**—The trustees of the Cincinnati City Hospital are framing a bill appropriating \$250,000 for the complete renovation, alteration and remodeling of the institution, which was erected in 1864.

**In Memoriam.**—The physicians of Caldwell met and passed resolutions eulogistic of the late Dr. John W. Brock. —At a special meeting of the Erie County Medical Society, resolutions were adopted regarding the death of Dr. Elwood Stanley, of Sandusky.

**The Cincinnati Hospital Training School** held its ninth annual commencement, January 15, graduating a class of seventeen. Addresses were made by Drs. C. A. Fackler and J. M. Withrow. The diplomas were presented by Mayor Fliessmann as president of the Board of Trustees, and the gold badges by Dr. C. R. Holmes.

**Hospital Donations.**—Samuel Mather, who has previously given large amounts to Lakeside Hospital, Cleveland, has arranged to give \$40,000 to the institution under easy conditions. —The mortgage on Huron Street Hospital, amounting to \$15,000, has been paid. John D. Rockefeller contributed \$5000 and Senator Mark A. Hanna \$4000 of this amount. —Youngstown City Hospital is to be endowed with \$50,000, the aggregate of one day's wages of several thousand workmen in the Mahoning Valley.

**To Revise Health Laws.**—The State Board of Health, at a recent meeting, approved the draft of a bill providing for a thorough revision of the state health laws. The proposed law makes many changes in the existing statutes. Among them is a provision requiring local boards and health officers to take all precautions against the spread of contagious diseases. It makes obligatory the posting of placards and the quarantining of patients. Another important change is the provision authorizing the councils of municipalities of less than 2000 inhabit-

ants to appoint a health officer to perform the duties now performed by local boards of health. Much difficulty is experienced in persuading citizens of small towns to serve on boards of health and the state board feels that much will be gained by laying the responsibility upon one man, who is paid for his services. The bill will soon be introduced in the legislature.

#### PENNSYLVANIA.

**Physicians to be Paid.**—At a recent meeting of the directors of the Cottage State Hospital, Connellsville, it was decided that the eight local physicians who for ten years have donated their services, be paid during their three-months' term of service, \$50 per month.

**Gifts to Hospitals.**—The United States Steel Corporation has donated \$1000 in cash and 2½ acres of coal land valued at \$2500 to the Uniontown Hospital Association. —The Philadelphia Hospital for Women is to receive \$3000 from the estate of the late Mrs. Rebecca S. Elkinson.

**Lancaster Hospital Staff.**—At the meeting of the directors of the Lancaster General Hospital the following staff was elected: Medical director, Dr. Martin L. Herr; medicine, Drs. Daniel R. McCormick, Frank G. Hartman and Harry G. Hasenplug; surgery, Drs. Theodore B. Appel, William H. Herr and Frank Alleman; ophthalmology, Drs. George R. Rohrer and Walter B. Weidler; laryngology, Dr. Walter S. Brenholtz; dispensary staff, Drs. Samuel H. Heller, Charles P. Starr and Guy Alexander, and neurology, Dr. Milton U. Gerhard.

#### Philadelphia.

**Alumni Association of the Medico-Chirurgical College.**—This Association has elected Dr. Mitchell P. Warmuth, president; Dr. Stillwell C. Burns, secretary, and Dr. Emanuel S. Gans, treasurer.

**Bequests.**—By the will of the late Wm. McClary, among charitable bequests are \$5,000 each to German, St. Joseph's, Samaritan, Episcopal and Presbyterian hospitals, for the endowment of free beds.

**Typhoid fever** increased to 117 new cases, against 81 for the previous week. The increase is chiefly in West Philadelphia, and is believed to be due to the water supply. The reservoir supplying this section is so small that little if any time can be allowed for sedimentation.

**Homeopaths Extol Vaccination.**—In a resolution recently adopted by the Germantown Homeopathic Medical Society, unqualified approval is expressed of the "value of vaccination as a preventive of smallpox;" the Society declares itself "heartily in accord with the Board of Health to secure universal vaccination."

**Tablet to Dr. Wilson.**—A handsome tile and marble tablet in memory of Dr. Charles Meigs Wilson has been unveiled at the Philadelphia Lying-in Charity and Nurse Training School, Eleventh and Cherry streets. The memorial was erected by the fourteen nurses who studied under Dr. Wilson when he was head physician of the school, and bears the inscription: "Erected by his nurses, in loving memory of Dr. Charles Meigs Wilson, who departed this life Dec. 29, 1891."

**Smallpox.**—There were 90 new cases and 19 deaths for the week ended January 27. The number of deaths equaled the highest number for any previous week. The Department of Public Safety has systematically undertaken to vaccinate the inmates of the hundreds of cheap lodging houses. Two or three of the physicians from the special vaccine corps will be sent at night to a certain house, in company with and under the protection of a detail of police. The latter are directed to see that none of the inmates leave the house until all are vaccinated or have been pronounced by the physicians to have a satisfactory vaccination mark.

**Library of College of Physicians.**—The Library Committee of the College of Physicians recently submitted its annual report. The number of volumes in the library is 64,916, an increase of 3557 during 1901. There were 211 donors during the year. By the bequests of Dr. John Ashhurst, Jr., and Dr. Alfred Stillé, 1500 volumes and 207 volumes respectively were received. Each of the following presented more than 50 volumes: Drs. T. G. Ashton, George F. Baker, H. A. Hare, J. K. Mitchell, S. Weir Mitchell, L. S. Clark, Francis R. Packard, E. P. Davis and W. B. Atkinson. Thirty-six of the new publications added to the library have been written or edited by Fellows of the College. By the liberality of a few Fellows of the College the collection of rare books made by the late Dr. J. Stockton Hough was secured. As indicating the rarity and value of this collection the librarian states: "Five hundred and

fifteen of the volumes were printed before 1700; 76 were printed in the 15th century, 175 in the 16th, and 264 in the 17th." The committee closes the report by saying: "Our library is believed to rank third among the medical libraries of the world, and is a valuable possession of which the Fellows of the College may well be proud."

#### TEXAS.

**Hospital at Reformatory.**—The superintendent of the Gatesville Reformatory has been authorized to construct a hospital for the institution at a cost of \$25,000.

**State Medical Association.**—The next meeting of the Texas State Medical Association will be held at Dallas, May 6 to 9. This is a change of date as well as place of holding the meeting, as it was originally intended to meet at El Paso.

**Deficit in Health Department.**—A heavy deficit has come to light in the State Health Department, and Dr. I. J. Jones, formerly secretary and assistant to State Health Officer W. E. Blunt, who, it is alleged, went to South America shortly after Dr. Taber was appointed to succeed Dr. Blunt, is wanted here, Dr. Taber says, to explain matters. It is alleged that, should he return, he would have to answer to charges of embezzlement and forgery.

**Headquarters Southern Pacific Hospital Department Changed.** By a recent order of the manager of the Southern Pacific Atlantic system, the headquarters of the hospital department have been transferred from San Antonio to Houston; the position of medical director has been abolished; Dr. Robert W. Knox has been appointed chief surgeon; and district, local and emergency surgeons, and others are ordered to report to him on all matters concerning hospital department.

**Must Report Contagious Diseases.**—The state health officer has sent to the county health officers throughout the state and to the city health officers in cities of over 10,000 inhabitants a blank form on which to report the number of cases and deaths from contagious diseases and the exact location of the cases. The following is a list of the diseases: Smallpox, varioloid, varicella, typhus fever, yellow fever, Asiatic cholera, typhoid fever, scarlet fever, diphtheria, measles, whooping cough, phthisis pulmonalis.

#### CANADA.

**Smallpox Epidemic.** Dr. J. M. Eaton, medical health inspector for the province of Manitoba, reports, on January 23, that there is an extensive outbreak of smallpox in the Winnipegosis district, which he has investigated, and states that there are upward of 200 cases. He considers the state of affairs to be alarming, as the whole district is virtually honeycombed with the disease. The outbreak is mostly among the half breeds and fishermen and it is mild in character.

**Ontario's Death Rate.**—The Registrar General for the province has handed out a statement with regard to the deaths occurring in the province of Ontario during the year 1901. Ninety per cent. of the population is represented in these returns. During the year there were reported 25,736 deaths, or 13.1 per thousand. The figures for the previous year were 25,382. Scarletina claimed 209; diphtheria, 512; typhoid, 345; tuberculosis, 2286, 74 less than in 1900; measles, 120; whooping cough, 112.

**Quarantine on the Coast.**—With the permission of Dr. Montizaambert, the Director General of Public Health, an important change in quarantine arrangements has been made affecting the Empress line of steamers plying between Vancouver and the Far East. Hitherto the liners have been obliged to go to the Williams Head station, and there remain from four to five hours, according to the number of passengers on board. Hereafter, the steamers will only be obliged to touch at the quarantine station when any contagious disease has developed on the voyage. Better connections will thus be made with the overland trains from Vancouver.

**A Woman's Hospital.**—Much progress is being made in connection with the proposal inaugurated two years ago to have a woman's hospital in connection with the Woman's Medical College, Toronto. Although the campaign thus far carried on has consisted chiefly in organization work for the purpose of making systematic collection of funds, and educational, there is said to be already a nice little sum in hand for the foundation of the enterprise. Nearly four years ago a dispensary was started in connection with the College, which up to the present time has had 9000 patients on its rolls; and it is the increasing demands on the dispensary that necessitates the having of a separate hospital in association with the college work.

**A Physician Jailed.**—About two months ago Dr. Harbottle, a practitioner of thirty years' standing of the town of Burford, Ont., while walking on the main street and being subjected to indignities at the hands of tormentors, deliberately shot one of his assailants, inflicting a small scalp wound. For many years the Doctor, who is spoken of as being eccentric, has been repeatedly subjected to insults and indignities on account of his outspoken sympathy for the Boers at the hands of residents of the town, the trouble has finally culminated in the Doctor taking the law in his own hands, with the result that he has been sentenced to one year's imprisonment in the Central Prison at Toronto, where he arrived last week. Dr. Harbottle has been assigned to the duty of assistant surgeon at the hospital. Efforts will be made to secure his liberation.

**Amending the Ontario Medical Act.**—Dr. Jessop, one of the members of the Ontario Legislature, has become the sponsor of a bill and at the same time the champion in the legislature of the Ontario Medical Defense Association. It is proposed to change the constitution of the Ontario Medical Council, which at the present time consists of 30 members. Of this number the homoeopathic body of the province, which only numbers about 40 practitioners, has 5 of a representation; the medical colleges, connected with Toronto University, Trinity University, Queen's University and the Western University at London have 8 between them, while the profession throughout the province has the balance, viz., 17, each of these representatives representing at least 250 physicians belonging to the regular profession. This is considered to be very unfair, and it is therefore proposed to abolish the homoeopathic and appointed representatives and have the entire 30 members of the Council elected by the whole medical profession of the province.

**Royal Victoria Hospital, Montreal.**—The governors of this institution held their annual meeting during the past week, when the announcement was made that an extension was to be made to the buildings in the near future, and among other things to be provided was a new operating theater for the gynecologic department. The following additional appointments were made to the staff: Dr. F. B. Jones was appointed assistant in the clinical laboratory. Dr. A. G. Nichols, assistant pathologist; Dr. G. P. Girdwood, director of the medical electrical department; Drs. H. B. Cushing and F. M. Fry, clinical assistants in medicine; Drs. A. Shirres and A. A. Robertson, assistants in neurology; Dr. E. A. Archibald, assistant in clinical surgery; Dr. F. W. Harvey, clinical assistant in ophthalmology; Dr. W. H. Jamieson, clinical assistant in laryngology; Dr. H. B. Yates, assistant in bacteriology; Dr. A. A. Briere, director of the clinical laboratory, and Dr. H. B. Cushing, medical registrar. During the past year there were admitted to the wards of the hospital 2579 patients, of which number 1254 were free patients.

#### LONDON LETTER.

##### The Smallpox Epidemic.

The number of cases of smallpox admitted to hospital continues to increase. The number of patients in hospital, which for the preceding 3 weeks were 506, 538 and 666 respectively, has risen in the last week to 872, during which 305 new cases were admitted against 161, 226, and 261 in the three preceding weeks. The greatest number admitted on any one day was 56. The numbers of deaths from the disease in the past 4 weeks have been 24, 24, 28 and 45. According to the latest returns there are 901 cases in hospital. At a meeting of the Metropolitan Hospitals Board an important report was presented. A number of new hospitals are being constructed as rapidly as possible so as to bring the total accommodation up to 2540 beds, and it is not at all certain that greater accommodation may not be required. The most important part of the report is the vaccination statistics. They tell only the oft-told tale, but in the face of the pernicious anti-vaccination propaganda, which has led to widespread neglect of vaccination, and is partly responsible for the epidemic, they are particularly opportune. The epidemic has now lasted five months, during which 1963 patients have been admitted to hospital. Of these 892 have been discharged recovered and 283 died. The cases have been divided into three classes: 1. vaccinated, i. e., cases showing visible cicatrices; 2. doubtful, which include cases stated to have been vaccinated but showing no visible evidence thereof and cases in which no statement was made but in which the eruption prevented observation as to the cicatrices; 3. unvaccinated, i. e., cases admittedly unvaccinated or bearing no traces of the operation and as to which no statement was made. The gross mortality is 24 per cent., but it must be borne in mind that many recent cases have been included be-

cause they were completed by death, whereas the contemporary cases which would nearly all recover, could not be included until completed. Thus the above figure is too high. The total mortality of the vaccinated cases is 14 per cent.; of doubtful cases, 65; and of unvaccinated cases 50.5. Considering the statistics according to age, under 10 there were only 12 vaccinated cases and no death; 6 doubtful cases, all of which were fatal, and 95 unvaccinated cases of which 52 (54.7 per cent.) were fatal. Under 20 there were 161 vaccinated cases, of which 3 (1.87 per cent.) were fatal; 12 doubtful cases, of which 7 (58 per cent.) were fatal; and 161 unvaccinated cases, of which 79 (49 per cent.) were fatal. There appears to be a distinct diminution in the protective power of primary vaccination after the age of 20, the death-rate rising from 9.85 in vaccinated cases between the ages of 20 and 25 to 28.95 in cases between 35 and 40. The neglect of vaccination is strikingly disclosed by one fact: 21 patients who had been employed in disinfecting work by the various local health authorities were admitted. Not one of them had been vaccinated since infancy. There were also admitted 2 sanitary inspectors, 2 dustmen, 1 undertaker, 1 medical officer of an infirmary who had not been revaccinated. Contrast this with the experience of the management of the smallpox hospitals and of the ambulances. All the persons employed are revaccinated on engagement. Of 2198 persons employed between 1884 and 1900, during which period 17,900 cases were received, only 17 contracted smallpox. Of these 13 were not revaccinated until after they had joined and 4 were workmen who had escaped medical observation. Not one of the hospital staff has ever died of smallpox, and not one has ever suffered from the disease for the past eight years.

#### The Journal of Obstetrics and Gynecology of the British Empire.

This new journal begins with the present year and will be published monthly. It is not published under the auspices of any society, but the members of the Obstetrical Society, which has a chronic feud with the British Gynecological Society, are its principal backers. It may be remembered that two years ago the latter attempted to organize an International Gynecological Congress in London, but was unable to do so in consequence of a boycott by the members of the former society who alleged that the organizers of the Congress were not sufficiently "representative." Thus the promoters of the new journal include a large proportion of the most important names in British gynecology and obstetrics, and the need of a journal devoted to these subjects which is not the mere record of the proceedings of a single society is obvious. The chief editor is Mr. Alban Doran, Surgeon to the Samaritan Free Hospital, who combines distinct literary ability with his special gynecological knowledge. With him are associated a number of distinguished collaborators in all parts of the empire. He is to be congratulated on a very excellent first number. The object is to make the publication a complete and impartial record of British obstetrical and gynecological practice and a summary of contemporary thought and achievement in obstetrics and gynecology throughout the world. The annual subscription is 25 shillings, and the publishers are Balliere Tindall & Co., 8 Henrietta St., Covent Garden, London. The first number shows great promise. The place of honor is occupied by "An Analysis of 100 Cases of Uterine Fibro-Myoma," by Dr. Cullingworth, Obstetric Physician to St. Thomas' Hospital, London.

#### Gastro-Enterostomy for Severe Hematemesis.

At the Edinburgh Medico-Chirurgical Society Mr. Alexander Miles showed a patient after gastro-enterostomy for severe hematemesis. A woman, aged 42, was suddenly seized with severe hematemesis. Four years previously she had been treated for dyspepsia, and the stomach, which was dilated, had been frequently washed out. She had never vomited blood nor exhibited any of the ordinary signs of gastric ulcer. She regained normal health and remained well until September 8, when the hematemesis occurred. The usual methods of treatment were unsuccessful in arresting the bleeding which continued for three days. As life was endangered, operation was advised. On opening the abdomen by a mesial incision a densely indurated ulcer of about the size of a 5-shilling piece was found close to the pylorus. It extended to the lesser curvature and fully two-thirds of the way to the greater curvature. It was therefore impossible to invaginate it without great risk of occluding the pyloric orifice, and the condition of the patient did not justify an attempt to excise the ulcer. It was therefore decided to perform a posterior gastro-enterostomy. After opening the stomach its interior was explored with the finger. No definite bleeding-point was recognized in

the ulcer. The communication between the stomach and the intestine was then completed with silk stitches. Before closing the abdomen about two pints of saline fluid were introduced into the peritoneum. During the first 24 hours after operation rectal injections of saline fluid were given every 4 hours and frequent nutrient enemata, which were all retained. The foot of the bed was raised. Although she continued to vomit bile-stained mucus at intervals there was no further loss of blood. Flatus was expelled in the evening. On the 12th she was better, though there was still sickness occasionally, but this became less frequent when the foot of the bed was lowered. On raising the head of the bed vomiting entirely ceased. On the 13th beef tea and peptonized milk were given per os. Recovery was uninterrupted.

#### Medical Treatment of Chronic Tuberculosis of the Intestine.

At the Clinical Society Mr. A. W. Mayo Robson read an important paper on this subject. He observed that whatever might be the views regarding the treatment of acute intestinal ulceration, surgical treatment is generally advisable in chronic intestinal tuberculosis. He related 7 cases (one male and six females) in which he had operated with only one death. In 2 cases the adhesions to adjoining parts were very intimate, in the others the affected parts of the bowel were quite free, thus rendering operative measures easy and simple. In 4 cases he employed his decalcified bone bobbin as a temporary splint over which to apply sutures. The physiological rest to the diseased parts secured by short-circuiting (as in one case) and by colotomy (as in another) seemed to answer so well that when the radical operation of excision involved serious difficulties or the patient was not in a condition to bear it he will not hesitate in future to be content with similar procedures and then to trust to general treatment and hygienic surroundings to assist in the cure. If in the future operative treatment be thought advisable in acute cases he anticipates that short-circuiting the diseased area will be found to be the more useful procedure, as it is the easier and safer, but experience alone will show whether the suggestions will prove of as much service in acute as they are in chronic cases. It is interesting that in 2 cases, in which tuberculous peritonitis coexisted with tuberculous ulceration of the intestine, the mere exploratory operation had not cured or even arrested the tuberculous process, but the radical operation of removing the principal focus of disease or the short-circuiting put a stop to the tuberculous peritonitis and, so far as could be seen, cured the more diffuse disease. All surgeons must have the experience of curing tuberculous peritonitis by simple abdominal section with or without drainage, and probably many of disappointment in cases in which the effusion had returned after a longer or shorter interval. He supposed that the explanation of these recurrent cases lay in the fact that the original focus of disease in the ovaries, Fallopian tubes, or bowel, had not been removed and again was the starting-point for a further effusion of the tubercle through the peritoneal cavity.

## Correspondence.

#### Death from Chloroform Anesthesia.

MANITOWOC, WIS., Jan. 26, 1902.

To the Editor:—In reading over Dr. Bayard Holmes' paper on "A Report of a Death from Chloroform Anesthesia," I am surprised at the ungenerous stand the Doctor takes in regard to the anesthetizer. After stating, "It has been my practice to have a skilful person administer chloroform, even if it necessitated an untried and even inexperienced physician as my first assistant," he, a little further on, takes comfort in the fact that the anesthetizer in this case was a stranger to him and untried. Why should that fact soothe, rather than trouble, his conscience, since he neglected to follow his own rule? The anesthetizer being a stranger and untried does not prove him unskilful. Death from anesthesia may be due to improper administration, to an unfavorable condition of the patient, or to an unfortunate choice of the anesthetic. It has been proven again and again that ether narcosis is the safer, and chloroform is usually substituted because it is administered more quickly and pleasantly.

Physicians practicing in the smaller cities can not always call an expert anesthetizer to their aid, and they are obliged

to call on a brother physician, a student, a trained or untrained nurse or a layman to take his place. In emergency cases the anesthetic is often administered by the surgeon in charge, who at the same time is his own first and second assistant and trained nurse; and deaths from ether or chloroform are as rare in their practice as under the care of the trained anesthetizer and score of assistants in the large hospitals.

The best of men have lost cases from the anesthetic, yet they have not been censured unless it was proven that they were criminally careless. Why, then, in this case, where no carelessness has been shown, should the anesthetizer be given the blame, while the surgeon coolly excuses himself with the statement that that assistant was unknown and untried?

The Doctor evidently had not recovered from his agitation when he wrote that a physician who had once given ether should never be allowed to give chloroform afterwards.

Yours respectfully,

WM. G. KEMPER, M.D.

#### Appendectomy—Surgical History.

CINCINNATI, O., JAN. 24, 1902.

*To the Editor:* Will you kindly publish the enclosed letter bearing on the subject of early operation in appendicitis, and oblige.

Yours respectfully,

B. MERRILL RICKETTS, M.D.

"FT. WAYNE, IND., JAN. 21, 1902.

"Dr. B. Merrill Ricketts, Cincinnati, O.

"*Dear Doctor:*—The enclosed clipping from THE JOURNAL of the American Medical Association was sent me this morning by my son, Dr. George C. Stemen, of Denver. ["Appendectomy—Surgical History," Page 46, this Volume.] I had overlooked this in reading THE JOURNAL.

"In regard to my case, I will say that on April 22, 1887, I was called in consultation to see a man said to be suffering from general peritonitis and called "perityphlitis." There was every indication that the man would die, and I said that if he would consent, I would operate on him. He not only consented but requested that it be done. I made the operation and found a large quantity of pus and a necrosed appendix almost detached. I removed it and drained, and the patient is living to-day. You misunderstood me when I met you at Lima, as to it being 1884; it was 1887. The gentleman I operated on is A. B. Nickey, who lives at Princeton, Ind., and is in good health.

"I thank you for mentioning my case. I am not much concerned as to whether I made the first operation, but I certainly made one quite early in the history of this operation.

"Respectfully yours,

"C. B. STEMEN, M.D."

#### The A. M. A. as Basis of Reciprocity.

CHATTANOOGA, TENN., JAN. 21, 1902.

*To the Editor:* I can not just at present go into a detailed consideration of defense of the proposition, but I wish to heartily endorse the suggestion made by Dr. Skelly in the last issue of THE JOURNAL, that membership in the American Medical Association be made the basis of reciprocity for license to practice between the various state examining boards.

With this as a foundation idea it seems to me that it is possible of elaboration so as to practically apply to this vexed question how to bar quacks and impostors, while at the same time recognizing intelligence, experience and probity towards license for practice throughout our common country, with as little of examination as may prove reasonable in compliance with laws as now existent or contemplated.

At some future date I may find opportunity for further argument on this point. At present I merely want to bring out further opinions upon the proposition, so that we may hear both sides of the question and ascertain how extensive may be the impulse to make this membership a basis for reciprocity, how practicable it is, what obstacles interpose, and how the examiners themselves receive the proposition. In a word let us "reason together" about the matter.

Yours,

E. A. CORLEIGH, M.D.

#### Tetanus Following Vaccination.

PHILADELPHIA, PA., JAN. 21, 1902.

*To the Editor:*—I will be greatly obliged to any of your readers who may have had or know of cases of tetanus following vaccination, if they will communicate with me concerning them. I am engaged in a critical analysis of such cases in the hope of determining their etiology, and desire to secure all the data possible.

Respectfully yours,

JOSEPH MCFARLAND, M.D.

#### Married.

GEORGE WESLEY BEATTY, M.D., of Brooklyn, N. Y., to Miss Caroline M. Steingester.

HARRY E. BUNDETT, M.D., to Miss Nellie O'Gara, both of St. Paul, Minn., January 8.

HERBERT BACON, M.D., to Miss Mollie Prouse, both of Bloomville, Ohio, January 19.

DWIGHT CALKINS, M.D., Battle Creek, Mich., to Miss Marjory E. Ryder, of Pittsburg, Pa.

CHARLES E. CONGDON, M.D., to Miss Anna Ramsdell, both of Nashua, N. H., January 16.

JAMES H. DAVIS, M.D., Seyppel, Ark., to Miss Inus Bishop, of Belton, Texas, Dec. 23, 1901.

WILLIAM S. BEATTY, M.D., to Miss Estelle Bonner, both of Vineyard, Ark., January 29.

WILMER ADAMS, M.D., Wye Mills, M.D., at Baltimore, to Miss Mamie R. Gould, January 15.

HENRY T. NORMENT, M.D., Anthoston, Ky., to Mrs. Virginia Norment, Henderson, Ky., January 16.

HERMAN S. SPEAR, M.D., New Portland, Me., to Miss Evelyn Conant, of South Strong, Maine, January 1.

FREDERICK PHINEAS DRAKE, M.D., London, Ont., to Miss Ada Kibbee Wright, of Port Huron, Mich., January 15.

WILLIAM N. MCARTNEY, M.D., Fort Covington, N. Y., to Miss Caroline Claghorn, assistant superintendent of the Lackawanna Hospital, Scranton, Pa., January 15.

#### Deaths and Obituaries.

Sylvester D. Bell, M.D. Western Reserve University, Cleveland, Ohio, 1874, formerly a practitioner of Butler, Pa., but for the past few years a resident of Arizona, a member of the Medical Society of the State of Pennsylvania and of the American Medical Association, died at his home in Tucson, January 14. He was a presidential elector in 1892, and had held several responsible territorial appointments.

Frederick Gundrum, M.D. Miami Medical College, Cincinnati, 1868, who had practiced for several years in Indiana, going thence to California on account of his health, died at his home in Riverside, January 13, from asthma complicating la grippe, after an illness of three days, aged 57. He was a member of the American Medical Association.

Kingston Goddard, M.D. University of Pennsylvania, Philadelphia, 1860, a contract surgeon in the Civil war, and thereafter for many years a practitioner of Philadelphia, coroner, and member of the Board of Education, who retired from active practice several years ago, died at the residence of his son in Philadelphia, January 18, aged 62.

James Farrington, M.D. New York University, 1847, one of the oldest physicians of Rochester, N. H., died at his home in that place, January 18, aged 80. He was a member of the Stratford District and New Hampshire State Medical societies and had served as a member of the legislature, of the constitutional convention and of the governor's council.

John Brownrigg, M.D. Jefferson Medical College, Philadelphia, 1851, formerly a surgeon in the Confederate service, one of the most prominent physicians of Mississippi, and a resident of Columbus, died January 21, at Mullanphy Hospital, St. Louis, where he had been under treatment for a long time, aged 72.

Warren Montgomery Sweetland, M.D. Rush Medical College, Chicago, 1848, for twenty-five years a resident and practitioner of Highland Park, Ill., who retired from active prac-

tice twelve years ago, died at his home, January 23, aged 82. He was a member of the American Medical Association.

**Joseph Abell Baden, M.D.** University of Maryland, Baltimore, 1856, a Confederate veteran and since the war a well-known physician of Calvert County and Baltimore, Md., died at his residence in that city, January 20, after an illness of one week, from heart disease, aged 68.

**Harvey Parkhurst, M.D.** University of Buffalo, N. Y., 1851, one of the oldest practitioners of McLean County, Ill., and a charter member of the County Medical Society, died at his home in Danvers, January 16, from heart failure, after an illness of only a few hours, aged 79.

**William Merwin Smith, M.D.** formerly health officer of the Port of New York, twice a member of the legislature, surgeon-general on the staff of General Dix and brigade surgeon during the Civil war, died at his home in Redlands, Cal., January 17, aged 75.

**W. C. Brown, M.D.** Rush Medical College, Chicago, for many years a practitioner of Geneseo, Ill., but more recently a resident of Sierra Madre, Cal., died at the Pasadena Hospital, January 12, from brain disease, after an illness of two weeks.

**Peter R. Furbeck, M.D.** Long Island College Hospital, Brooklyn, 1865, for many years a leading practitioner of Gloversville, N. Y., died at a sanatorium in Saratoga Springs, January 17, from Bright's disease, after a long illness.

**Louis J. Archambeault, M.D.** Laval University, Quebec, 1870, formerly a practitioner of Cohoes, N. Y., but for the last three years a resident of Brooklyn, died at his home in that city, January 12, after a brief illness, aged 54.

**Harry Peters, M.D.** University of Iowa, Iowa City, 1896, who commenced practice in Minden, Iowa, but moved to Davenport in 1900, died at his home in that city, January 16, from diabetes after a protracted illness, aged 30.

**Charles Winston Spencer, M.D.** Jefferson Medical College, Philadelphia, 1857, who practiced for more than 30 years at Plattsburg, Mo., died at Elvens, St. Francois County, Mo., January 6, after a brief illness, aged 67.

**Prof. Emil Scheffer,** a well-known chemist of Louisville, Ky., who discovered the formula for making liquid pepsin and also that for the preparation of dry or powdered pepsin, died, January 22, aged 80.

**George M. Wellman, M.D.** University of Georgetown, D. C., 1868, and since that time an esteemed practitioner of Dover Plains, N. Y., died at his home in that place, January 13, aged 65.

**Harry D. Kline, M.D.** Northwestern Ohio Medical College, Toledo, 1890, president of the King County (Wash.) Medical Society, died at his home in Seattle, January 19, from pneumonia.

**Samuel O. Prall, M.D.** University of Pennsylvania, Philadelphia, 1897, a practitioner of Easton, Pa., died at his home in that city, January 16, after a short illness, aged 30.

**Augustus Hibler, M.D.** University of Freiberg, Baden, 1852, one of the oldest physicians in Center County, Pa., died at his home in Bellefonte, January 16, aged 72.

**William Wixom, M.D.** Geneva (N. Y.) Medical College, 1846, a life-long resident of Italy Hill, N. Y., died at his home in that place, January 15, aged 83.

**Henry E. Watkins, M.D.,** of Prince Edward County, Virginia, died at his home near Farmville, Va., January 16, after a long illness.

**Eleazor Price, M.D.** University of Buffalo, N. Y., 1855, an old resident of Jackson, Mich., died at his home in that place, January 18.

## State Boards of Registration.

The North Carolina Board of Medical Examiners will hold its regular meeting in Wilmington, Thursday, May 29, at 12 m.

**Minnesota Board of Medical Examiners.**—This Board has issued the following notice: After January 1, 1902, applicants for license to practice medicine and surgery in the State of Minnesota must present evidence of having attended four full courses at a medical college recognized by the Minnesota State Board of Medical Examiners, of at least twenty-six weeks each, no two courses being in the same year. Graduates of medical

colleges granting advanced standing for work done at other than medical colleges shall not be eligible to the examinations given by this Board. Provided, that above shall not apply to such students as have been granted advanced standing prior to September, 1901. By order of the Minnesota State Board of Medical Examiners, C. J. Ringnell, M.D., secretary.

**North Dakota Examination.**—The North Dakota Medical Examiners held their regular quarterly examination, January 7, at Grand Forks. The number of subjects examined in were 13; number of questions (?). Percentage required, 75. The number of applicants were 12, of whom 7 passed.

## Book Notices.

**THE LIFE OF PASTEUR.** By René Vallery-Radot. Translated from the French by Mrs. R. L. Devonshire. Vols. I and II. Cloth. Pp. 292 and 336 respectively. Price, \$7.50. New York: McClure, Phillips & Co. 1902.

This is more than a life of Pasteur—it is a history and a description of his work. But little space in the two volumes is devoted to his private life, yet enough to give us a good insight into the man as a husband, father and friend. It is written by his son-in-law and thus has the added value of being authentic and reliable. Pasteur's origin was a most humble one, his father being a tanner and not blessed with much of this world's goods. But he inherited a strong constitution, immense will-power, indomitable courage, and a determination that enabled him to overcome all obstacles when he set out to accomplish a purpose. Yet when he went to Paris at 15 years of age, with the *Ecole Normale* in view, and entered on his studies in Barbet's preparatory school, he became so homesick that it was necessary to send for his father to take him home. So for the time he resumed his studies, at a school nearer home, and his drawings—for at that time he made more promise of being a portrait painter than anything else. Considering his achievements in chemistry later on, it is interesting to read that in his examination before the Dijon Faculty in 1842 he was put down as *mediocre* in that branch. In the autumn of that year, when

he was 20, he again went to Paris and began a work, the result of which is known the world over. Step by step of that work is shown; details of his methods, so far as they could be understood by the lay reader, are given, and how that restless, determined genius saved to agriculturalists of his country millions of money. It tells how he reclaimed the silk, the wine and the stock industries of his native land, how for a time he was handicapped for want of material to work with and a place to work in, but how finally he was appreciated by his countrymen, who erected to him that noble memorial, the Pasteur Institute.

While written for the laity, this life will appeal especially to physicians, from the fact that it is a biography of the greatest scientific light of our age, a light that has illumined and opened the way to immense possibilities in medicine, in surgery and in biology. We wish the price were so low that the poorest member of our profession might obtain and read it, and especially that it could be put into the hands of every young man as he enters his medical career. If nothing more, it would be a stimulus to effort. This work and the "Life of Paget," which we noticed a few weeks ago, would make a magnificent foundation for a "working" library for any young man entering medicine.

**GYNCOLOGICAL PATHOLOGY.** A Manual of Microscopic Technique and Diagnosis in Gynecological Practice for Students and Physicians. By Dr. Carl Abel, Privat-Docent in Berlin. Translated and Edited by Samuel Wyllie Bandler, M.D., Adjunct Gynecologist to the Beth Israel Hospital, New York. With a chapter on the Embryology of the Female Genitalia and the Pathological Growths developing from Embryonal Structures. Illustrated by 100 engravings. New York: William Wood & Co. 1901.

**OUTLINES OF GYNCOLOGICAL PATHOLOGY AND MORBID ANATOMY.** By C. Hubert Roberts, M.D. Lond., F.R.C.S. Eng., M.R.C.P., Physician to the Samaritan Free Hospital for Women, Physician to Out-Patients, Queen Charlotte's Lying-in Hospital, Late Demonstrator of Midwifery and Diseases of Women, St. Bartholomew's Hospital. With 151 Illustrations, Mostly Original. Philadelphia: P. Blakiston's Son & Co. 1901.

Of these two books on practically the same subject the first contains 237 pages, the second 332, but the smaller type and larger page of the first make the two works of about the same extent. The general tendency of Abel-Bandler's book is to be a guide in microscopic technique and diagnosis in gynecologic practice. The fundamental value of the microscopic examination in the early diagnosis of many gynecologic conditions, but especially in carcinoma of uterus, is emphasized in the translator's introduction. In few diseases is an early diagnosis so important to the patient as in suspected carcinoma of the uterus and as the general practitioner commonly is the first called upon by the patient the responsibility rests upon him and he must make the test excision or test curettage. This illustrates well enough the general tendency of the book and the point of view from which the matter in it is presented. The portion on technique is sufficiently extensive and detailed to answer the purpose. The second part on diagnosis takes up the various organs concerned and, beginning with the normal anatomy of each organ, carefully describes the pathologic anatomy under the usual headings. Part III, added by Bandler, reviews the embryology of the female genitalia and gives a discussion of the pathologic growths that develop from them. This part is a valuable addition to the original work, as it brings together in one place a number of interesting facts that help one to understand the complex conditions encountered in this part of the body. The illustrations represent the actual microscopic appearances very well. The book has a distinct field in which it will be found of definite value to the student as well as the practitioner.

The chief object of Dr. Roberts's work is to present "as simply as possible the morbid processes to which the female organs are subject." The author has endeavored to give the more modern views of British pathologists. References to both British and foreign authors are plentiful, and occur at the bottom of the pages. Numerous original illustrations have been introduced, and in each case the place where the original specimen may be found is stated, a feature of much value to students of medicine frequenting the hospitals in the museums of which the specimens are preserved. The greater number of the illustrations, which are placed upon separate leaves throughout the body of the work, represent the gross appearances of pathological specimens and the method of reproduction

is quite successful. The book is not strictly confined to the pathological anatomy of the female genitalia; a certain amount of clinical material is introduced, e. g., vaginismus, menstruation and its disorders, sterility. The diseases of the bladder, urethra, and uterus are also presented. The last chapter deals with micro-organisms in relation to diseases of women. In this chapter is discussed also the question: "Is there a parasite of cancer?" It seems to us that a better arrangement might have been desired, and that etiology and pathological anatomy are best discussed together. The general arrangement of the material in Gebhard's book, for instance, seems to us to present certain natural advantages, at least in some respects. The information conveyed in the last chapter in regard to ordinary pathogenic organisms is decidedly elementary, but at the same time there is not enough of it to be of any real service to the student who naturally is supposed to be well grounded in the principles of general pathology and bacteriology before he takes up the special study of gynecologic pathology. The discussion of tumors is not altogether satisfactory because "adenoma malignum" is separated from carcinoma, to which it belongs, and because "deciduoma malignum" is classed definitely with sarcoma. The differences of opinion concerning the nature of "deciduoma" is well shown by the list of names proposed for it: Abel gives no less than fourteen. The statement concerning this interesting tumor, or group of tumors, in either of these works is not quite as exhaustive and critical as one would be likely to look for in works of this kind. The treatment of ovarian teratomas or embryomas by Roberts is also disappointing as they are not clearly described and no detailed reference is made to the recent interesting studies of this class of tumors by Wilms and others. The statements in regard to the theories of the origin of the dermoid cysts and teratomas are very meager. In the index there is no reference to actinomyces of the female genitals nor to certain rare but interesting metaplastic changes in the uterine epithelium, at least not under the ordinary headings.

The attention given to illustrations of gross pathological specimens is probably the chief distinguishing feature of Roberts's book; but it is lacking in real grasp and critical discussion of questions of fundamental importance in gynecological pathology, and it does not aim to be a guide to technical work.

## Miscellany.

**Asbestos Dishes for Consumptives.**—F. Kornfeld, of Vienna, exhibited at the local medical society, December 6, a number of articles made for the use of consumptives out of asbestos: cuspidors, dishes, etc. They can be sterilized without injury by putting them in the fire, and can be made at a trifling expense.

**Spontaneous Expulsion of a Fibroma in Esophagus.**—Sarkisoff relates in a recent issue of *Vratch* that a woman 27 years of age had experienced pain when swallowing, with some difficulty in breathing, and became fatigued easily. These symptoms continued for two years when she suddenly coughed up a fibroma 4 cm. long by 2 wide and .5 thick.

**New Complete Edition of Galen's Works.**—The Berlin and the Copenhagen Academy of Sciences have commenced the task of collecting all the manuscript left by Galen and compiling a new and complete edition of his works. The committee in charge, the "corpus veterum medicorum," expects to reap a rich harvest for philology and the history of medicine.

**Reposition of Prolapsed Umbilical Cord.**—H. Henne writes to the *Corr. f. Schweiz. Aerzte*, of December 1, describing a case of prelapse of the cord in which the placenta was attached unusually low, while the cord was exceptionally long—fully 130 cm. All attempts to reduce it proved unavailing until he applied a gauze compress and pushed the cord and fetal head back into the uterus, leaving the compress in the uterine cavity to protect against further prolapse. Labor and delivery proceeded normally and the compress was expelled with the afterbirth.

**Souvenir Medallion for Fournier.**—Professor Fournier retires from the clinical chair in the Hôpital Saint-Louis, Paris, at the close of the current scholastic year. His friends are soliciting subscriptions for the purpose of presenting him with a medallion to be designed and executed by Chaplain. A subscription of twenty-five francs forwarded to the treasurer of the fund, M. Rueff, 106 Boulevard Saint-Germain, Paris, entitles the subscriber to a copy of the medallion.

**Absorption of Food by the Intestines.**—Experiments with cooked, chopped and salted thymus gland administered by rectal injection, showed much greater absorbing power on the part of the intestines than they are usually credited with. A much larger proportion of uric acid and phosphates and also nitrogen, was excreted in the urine during the period of the tests. This was accepted by Mochizucki—who describes his research in the *Archiv f. Verdauungskr.* vii, 3—as evidence that the albuminoids and proteids in the enema must have been absorbed to a considerable extent.

**Pneumaturia.**—Wildbolz describes a case of pneumaturia, the last portion of the urine accompanied by air rushing out of the urethra. There was no pain, merely a slight tickling in the urethra. The patient was a man of 52. For the last few months he had felt weak, with headache and slight vertigo at times. There was no sugar in the urine, but 1.5 per 1000 of albumin. Wildbolz succeeded in isolating from the urine the bacterium *lactis aerogenes*, and established that this bacterium generates an odorless gas in the presence of albumin. All the symptoms disappeared when the patient was put on a nephritic diet and the albuminuria had vanished.

**Prophylaxis of Syphilis in France.**—The minister of the War Department of France has ordered that one of the lectures on hygiene delivered regularly by the medical officers to the officers and non-commissioned officers of the troops, shall be on the subject of the dangers of syphilis and the means of combating them. Young soldiers who conceal their infection are to be punished. The department of the interior has also taken up the matter and Waldeck-Rousseau has appointed a committee to study the various questions in regard to the prophylaxis of syphilis and venereal diseases. It includes fourteen physicians, Brouardel, Roux of the Institut Pasteur, several who are members of the legislature, officials on boards of health and hospital management, and the prefect of police, with Professor Fournier as the chairman of the committee.

**Physicians Who Oppose Vaccination.**—The recent occurrence of smallpox in the families of a number of physicians who oppose vaccination is a most serious matter. It is said that "vaccination by the mouth," or "by the stomach," is the method advised by them. Such phrases, according to science, betray an obstinacy that is worthy of punishment. We can find some excuse for layfolk, wholly ignorant of physiology, history and statistics, who oppose vaccination, but in physicians there is no excuse whatever. The testimony as to the value of vaccination is so overwhelming that those who do not admit it have no right to pass from the sick-room of patients with highly infectious diseases and scatter the germs among the people. Such physicians should be quarantined with their patients. Argument will have no effect upon such minds, and the swift punishment of their delusions by the occurrence of smallpox in themselves or in their families will have no influence upon their views or in their advice to their patients. In the name of medicine, to oppose the best established medical truth, and, in the name of therapeutics, to scatter disease is an outrage upon the community.—*American Medicine.*

**Permanently Cured Case of Ichthyosis.**—Bockhart has made many attempts to cure ichthyosis but has never found the patient persevering enough to accomplish a permanent cure except in the one case described. This was the 8-year-old daughter of well-to-do parents, who patiently for nine years rubbed her with sulphur salve three times a day. She was educated at home on account of the odor of the sulphur, and is now a young woman, who for nearly six years has been entirely free from the ichthyosis, which at first extended over the entire body, except the head, face, joints, soles and palms.

After a warm bath with soap in the morning a 5 per cent. sulphur salve was rubbed and massaged into the skin, and again at noon and night. Cod-liver oil was given internally, and twice a year for six weeks Kreuznach salts were added to her bath water. After three years the cure seemed to be complete and treatment was suspended for three months when recurrence was evident. After three years more, the child remained healthy for six months before the recurrence appeared. Treatment was resumed for another three years, since which time she has been permanently cured. In his communication to the *Monatssch. f. Prakt. Derm.* of December 15, Bockhart states that ichthyosis in adults is more rebellious than in the young.

**Teach Students the Importance of Organization.**—Dr. J. C. M. Floyd, of Steubenville, in a letter makes the suggestion that medical students should from time to time during their course of study be instructed as to the value to themselves of joining a medical society as soon as they enter upon practice. This is a matter worth some attention from medical teachers. It would not be difficult for every teacher to find at least one opportunity in a few words to point out to his classes the advantages to physicians of medical society membership. The utilitarian side of the matter, in that a live medical society constitutes a means for the ambitious young physician further to pursue his search for medical knowledge, needs few words to bring conviction to the student's mind. The value of friendly association in reducing the friction that often arises between men in active practice also is readily demonstrable. Then a few words might very profitably be devoted to stating the duty that medicine owes to the public to initiate measures directed to reducing the amount of preventable disease. There are some medical teachers who have followed this plan, but they are the exceptions. It is hoped that many others will by this suggestion be led to find an opportunity for directing the attention of their students to the benefits of medical organization.—*Cleveland Journal of Medicine*, Dec., 1901.

**Frequency of Embolism in Heart Disease.**—Ginsburg reports in the *Deutsche Arch. f. Klin. Med.*, lxi, 5 and 6, that he found in looking over the records of 250 autopsies of heart disease, that embolism had been noted in 85 cases, usually in the kidneys. Both kidneys were affected in 41 out of 62 cases. The clinical symptoms had not been severe: only hematuria in 4; albuminuria in 26 and tube casts in 5. Embolism of the spleen was noticed in 23, and it occurred without symptoms in 14, with tumefaction in 9. Two of the latter had complained of sudden, violent pains in the region of the spleen. In 15 cases the embolism was in the brain. It occurred suddenly in 9 without premonitory symptoms of disturbed compensation. One patient survived three years, 5 from ten to forty-five days, and 9 died at once. In 9 of these cases the heart affection was a mitral endocarditis, in 2 an affection of the semilunar valves, in 2 myocarditis with thrombosis of the left ventricle and in 2 a lesion of both mitral and semilunar valves. In one of 3 cases of embolism of the celiac trunk, hematemesis and bloody stools had been noted but no pain; in another there were violent pains in the abdomen and meteorism but no vomiting nor diarrhea. In the third, no symptoms suggested the celiac lesion.

**Revocation of Licenses to Practice Medicine.**—We should endeavor to shunt the rage of the antis upon the lawyers. At present the medical profession is the object of the most violent hatred of the hordes of quacks and medical anarchists, on the ground that medical men are forming a trades union. It is the wildest bit of silliness imaginable, and yet it dictates pernicious legislation and prevents medical progress in a thousand ways. Why do we lie under the imputation and find ourselves made to prove that the antis lie all about it? Simply because of our lack of professional *esprit de corps* and organization. Are the lawyers so foolish? By no means! Who ever heard of a doctor having his license revoked, no matter what egregious professional crimes he had committed? We allow every wretch who has ever stolen the degree of M.D. to retain it, although every word he writes or utters is loaded with venom against us, and destructive of every principle of medical decency and progress. What provision or machinery does there exist in the state laws for expelling a physician playing scamp? Do

medical societies turn him out? In every state lawyers who have disgraced their profession are disbarred, and yet the anti's do not rail at the legal profession as a trades union. Last year in Colorado 13 lawyers were disbarred; have 13 doctors ever had their licenses revoked in the whole United States in our entire history?—*American Medicine*.

**Physiologic Effects of Spinal Cocainization and Lumbar Puncture.** Pitres and Abadie describe the physiology of spinal cocainization as studied in detail on fifty patients and reported in the *Archives de Neurologie*, xii, 70. They attribute the analgesia to the action of the cocain in modifying the conductivity of the sensory roots, not to any action on the cord itself. They found that reflexes previously normal were exaggerated, while exaggerated or weak reflexes were abolished. Two thirds of the patients had trembling of the feet or knees, and in a few hysterics the tremor was general. The patients were always able to stand erect, free from ataxia, but walking was occasionally difficult, as their legs felt heavy, they said. The skin did not alter its color over the area of analgesia; pricking did not bring blood and even a sinapism caused no sensation of heat nor redness, while the same sinapism applied outside of the area of analgesia always induced the usual reaction. The skin remained dry and could thus be sharply defined from the sweating skin beyond the area of analgesia. Study of the physiologic effects of lumbar puncture on fifteen other patients showed that the headache occasionally observed after spinal cocainization is probably due merely to the puncture, and not to any toxic action of the drug, as it was a constant accompaniment of lumbar puncture, identical in appearance, localization, duration, intensity, etc., with that which follows spinal cocainization. None of the other symptoms were noted after lumbar puncture; nausea and vomiting were the rare exception.

**The Osteopathy Bill.**—There is a bill before the [New York] Legislature intended to license so-called osteopaths to practice medicine, treat contagious diseases, sign death certificates, etc. Such a bill naturally breaks down all the barriers in process of erection for scores of years to safeguard the people against malpractice, to protect the sick from the sort of vampires bred in new countries where the laws regulating the practice of medicine are apt to be liberal, not to say loose. New York, after decades of hard work on the part of philanthropists, medical, legal and other, has secured a code of laws regulating the practice of medicine in the rigid and impartial manner which has been found to be the best by a slow process of evolution in older countries. The law simply requires in the applicant for a license to practice a certain standard of education in the different branches of science with which medicine and surgery are concerned, in order that the public may be protected from the kinds of malefactors who in the absence of such wise legal provision would prey upon the sick. This standard of education is within the reach of any one. No one is debarred from acquiring sufficient knowledge to pass the examinations. The "regular" physicians must pass them. The homeopaths pass them. The "eclectics" pass them. If the so-called osteopaths pass them, they also would be equally privileged to practice. But what they desire is the right to practice medicine without passing any examination, without demonstrating, as all others of whatever school are required to do, their fitness to undertake the healing art. It would be just as fitting and proper that the practitioner of massage should have a law of this kind framed for him, for the masseur is usually extremely well versed in some of the principles underlying medicine. He is well acquainted with anatomy and physiology. The fact is that osteopathy is only a rudimentary form of massage. The word means bone cure and the osteopathist tells his patient that a small bone in the head or spine is out of place and he will pummel it into place at \$100 per month. It is a passing fad. In twenty years it will be laughed at along with the imbecilities of the Perkins tractors. Let the osteopath practice along with the masseur and the midwife and the nurse, but do not throw open the doors to the practice of the entire healing art.—*N. Y. Sun*, Jan. 21, 1902.

**Massage and Osteopathy.**—The founding of a special school of medical practice called osteopathy directs attention anew to the value of manipulation in the treatment of certain diseased conditions. Some have described osteopathy as a highly scientific massage; but the ordinary rubbing, kneading, and tapping prescribed in the works on massage and practiced by masseurs are very different things from the manipulations of the osteopaths. The latter are based upon the anatomical structures to be treated; sufficient force is employed to affect the deeper tissues. In improving the circulation, relieving pain, and absorbing inflammatory exudates by manipulation, the average osteopath is capable of teaching the profession valuable lessons. Of course, the foundation of a school of medicine upon such a narrow therapeutic resource will ultimately bring the whole movement into discredit, and perhaps a valuable method of treatment in a certain class of cases may fall into disuse. Had osteopathy confined itself to a legitimate application of its methods, and not attempted such absurdities as the "reduction" of typhoid fever by pressing upon the seventh cervical vertebra, it would probably have left a valuable impression upon the practice of medicine. Its fallacies will sink whatever is of good in the method. In Japan the blind are trained in massage. In Leipzig a number of blind people have been trained to the occupation. The massage that is taught is the ordinary rubbing and kneading and stroking with which most bath attendants are familiar. It is useful in general neurasthenic states and where a general improvement in the nutrition of the tissues is sought, or as a form of passive exercise in patients who are inactive. Such massage differs from manipulations based upon a careful appreciation of the anatomic elements involved in the structures which are treated, and knowledge of the vascular and lymph channels. It is unfortunate as well for the laity as for the profession that such manipulative methods have ever been allowed to pass into the hands of empirics. In Austria massage by the laity has been discouraged; it is in the hands of medical students and young medical men. In some way physicians have thought that such manipulations were beneath the dignity of the profession. This must be a relic of the time when the operation for stone was considered one that a surgeon should never perform. No one is so competent to deal with the adhesions in a joint and inflammatory exudates in the pelvis as physicians themselves. Indeed, there are many reasons for thinking that the physician alone is competent, as he is able to appreciate such dangerous infections as tuberculosis, which might be aggravated by manipulation. Massage and manipulative measures generally should be restricted to the profession. The older members whose time is too fully occupied to give the personal attention required in these cases should enlist the younger members of the profession in the work. When the profession fully awakens to its responsibility in this respect, much of the quackery which now flourishes will find itself relegated to the rear.—*Medicine*.

## Societies.

**Society of Physicians and Surgeons of Louisville.**—At the annual banquet, held January 16, Dr. Charles W. Hibbitt was elected president, and Dr. S. J. Myers, secretary.

**Platte County (Neb.) Medical Society.**—This Society was organized at Columbus, January 20, with Dr. Harry J. Arnold president, and Dr. Berthold Tiesing, secretary. The first annual meeting will be held February 12.

**Springfield (Mo.) Medical Society.**—At the annual meeting of this Society, Dr. Leander Cox was elected president; Dr. William M. Smith, vice-president; Dr. John R. Boyd, secretary, and Dr. Dexter B. Farnsworth, treasurer.

**Passaic (N. J.) Medical Society.**—At the annual meeting of this Society, January 9, Dr. Robert R. Armstrong was elected president; Dr. John J. Sullivan, vice-president; Dr. Frank M. Stagg, secretary, and Dr. Hiram Williams, treasurer.

**Medical Association of Troy (N. Y.).**—This Association met, January 7, and elected Dr. John W. Morris, Troy, president; Dr. Thomas C. Church, Valley Falls, vice-president, and Dr. Edward W. Becker, Troy, secretary and treasurer.

**Talladega County (Ala.) Medical Society.**—At the annual meeting of this Society held in Talladega, January 7, Dr. Jason S. McCants, Talladega, was elected president; Dr. Albert C. Sims, Renfroe, vice-president, and Dr. William G. Harrison, secretary.

**Riverside County (Cal.) Medical Society.**—At the quarterly meeting of this Society held at Riverside, January 14, Dr. Louise Harvey Clarke was elected president; Dr. Samuel Outwater, vice president, and Dr. Charles W. Girdlestone, secretary, all of Riverside.

**Rensselaer County (N. Y.) Medical Association.**—At its annual meeting held in Troy, January 7, Dr. Charles S. Allen, Rensselaer, was re-elected president; Dr. Thomas C. Church, Valley Falls, vice-president, and Dr. Frederick A. Smith, Troy, secretary and treasurer.

**Pettis County (Mo.) Medical Society.**—At the meeting of this Society, January 6, at Sedalia, Dr. William G. Cowan was elected president; Dr. Everett A. Wood, vice-president; Dr. Emory F. Gresham, secretary, and Dr. William H. Evans, treasurer, all of Sedalia.

**Summit County (Ohio) Medical Society.**—On January 15 this Society elected and installed the following officers: Dr. Charles E. Held, president; Dr. L. B. Humphrey, vice-president; Dr. Edward A. Montenyohl, secretary, and Dr. Charles E. Norris, treasurer, all of Akron.

**Nevada State Medical Society.**—This Society met in Reno, January 6. Dr. Anthony Huffaker, Carson, was elected president; Dr. Pinning, Floriston, vice-president, and Dr. A. E. Hershiser, Reno, secretary and treasurer. The next meeting will be held in Virginia City, July 7.

**Pawtucket (R. I.) Medical Society.**—This Society held its first annual meeting and banquet, January 7, at which Dr. William H. Heimer, Pawtucket, was elected president; Dr. Thomas H. McNally, Central Falls, vice-president; Dr. Joseph Duxbury, secretary, and Dr. Forrest Badger, treasurer.

**Olmsted County (Minn.) Medical Association.**—At the annual meeting of this body held in Rochester, January 13, the following officers were elected: Dr. John G. Cross, Rochester, president; Drs. Oscar C. Heyerdale, Rochester, and R. H. Russell, vice-presidents, and Dr. H. Speier, treasurer.

**Philadelphia Academy of Surgeons.**—At a recent meeting of the Academy the following officers were elected: Dr. Richard H. Harte, president; Drs. Henry R. Wharton and John B. Deaver, vice-presidents; Dr. William J. Taylor, secretary; Dr. William G. Porter, treasurer, and Dr. John H. Gibbon, recorder.

**Clark County (Ohio) Medical Society and the Academy of Medicine** held a joint meeting, at Springfield, January 15, over 50 being present, the object being to combine for more effective work and in accord with the plan recommended by the American Medical Association. A banquet followed the scientific work.

**Mahoning County (Ohio) Medical Society.**—At the annual meeting of this Society, held in Youngstown, January 7, Dr. Carlos C. Booth was elected president; Dr. John S. Zimmermann, vice-president; Dr. Charles D. Hauser, secretary; Dr. Jared E. Cone, treasurer, and Dr. George S. Peck, librarian, all of Youngstown.

**Savannah (Ga.) Medical Society.**—At the annual meeting of this Society, held January 15, Dr. Ralston Lattimore was elected president; Dr. Marion X. Corbin, vice-president; Dr. Ralph M. Thomson, recording secretary; Dr. George R. White, treasurer; Dr. J. Lawton Hiers, corresponding secretary, and Dr. Elton S. Osborne, librarian.

**Milwaukee (Wis.) Medical Society.**—This Society held its annual meeting, January 14, at which the following officers were elected: Dr. G. Frederick Shimonek, president; Drs. Carl Zimmermann and John W. Coon, vice-presidents; Dr. Arthur T. Holbrook, secretary; Dr. Wianus O. B. Wingate, treasurer; Dr. Louis F. Frank, librarian, and Dr. John M. Belfel, curator.

**Omaha (Neb.) Medical Society.**—This Society, at its annual meeting January 14, elected the following officers for 1902: President, Dr. Frank E. Coulter; vice-presidents, Drs. Joseph C. Moore and H. P. Hamilton; secretary, Dr. Joseph M. Aiken; treasurer, Dr. Millard Langfeld, and censors, Drs. Harry M. McClanahan, Benjamin F. Crummer and Andrew B. Somers. The Society has a membership of 79.

**Medical Club of Philadelphia.**—This Club held its tenth annual meeting January 17, at the Hotel Bellevue. Dr. E. L. Duer was re-elected president and other officers elected were: Vice-presidents, Drs. Thomas H. Fenlon and A. McAllister;

secretary, Dr. Guy Hinsdale; and treasurer, Dr. F. Savary Pearce. The club is purely for social purposes, has 365 members and a sinking fund of more than \$5000. It is the purpose to build a club house.

**Washington (D. C.) Medical Society.**—At the meeting of the Society held January 15, Dr. A. F. A. King read the essay of the evening, entitled "A New Factor in the Etiology and Treatment of Malarial Fever: Destruction of the Parasite by the Ultra-Violet Rays of Fluorescent Light." Dr. King demonstrated his theory and gave the results of his personal experiments. The discussion of the paper will be taken up at the next weekly meeting of the Society.

**Nashua (N. H.) Medical Association.**—On January 8, this Association held its annual meeting at which a valuable Morris chair was presented to Dr. Alonzo S. Wallace, who had granted the use of his office as a meeting-place for several years; resolutions regarding the late Dr. Royal B. Prescott were adopted and the following officers were elected: Dr. George F. Wilber, president; Drs. Sam S. Dearborn and August Guertin, vice-presidents; Dr. Ella Blaylock-Atherton, secretary, and Dr. Charles E. Congdon, treasurer.

**Orange County (N. Y.) Medical Association.**—This Association held its annual meeting at Middletown January 15, at which the following officers were elected: Dr. Milton C. Conner, Middletown, president; Dr. Frank W. Dennis, Unionville, vice-president; Dr. Charles I. Redfield, Middletown, secretary and treasurer; Dr. Edward D. Woodhull, Monroe, delegate to the American Medical Association; Dr. Charles E. Townsend, Newburgh, alternate, and Dr. William E. Douglas, Middletown, member of the council of the New York State Medical Association.

**Washington (D. C.) Obstetrical and Gynecological Society.**—At the semi-monthly meeting of the Society, held January 17, Dr. Joseph Tabor Johnson read the essay of the evening, entitled "Choice of Operation for Retro-displacements of the Uterus." Dr. Johnson presented the subject in its entirety and up to date, and the paper was fully discussed by the members. Dr. Stone reported a case of calculus lodged in the right ureter of a woman which was removed by abdominal section. Previous to the operation the diagnosis of appendicitis was made. The patient made an uneventful recovery. He exhibited the calculus, and an interesting discussion followed.

**State Sanitary Association (Minn.)**—The state sanitary conference which met, January 15, at St. Paul, effected a permanent organization with Dr. Henry M. Bracken, St. Paul, president; Drs. John M. Robinson, Duluth; Alfred E. Spaulding, Luverne, and J. J. Flatten, State University, vice-presidents, and Dr. Emory H. Bayley, Lake City, secretary. The conference discussed diphtheria, smallpox and rabies and passed resolutions recommending the establishment of a national department of health with a cabinet officer at its head.

**Philadelphia County Medical Society.**—On January 15, this Society held its annual business meeting. The Society has now 790 members, 7 having died within the year. The balloting resulted in the election of 36 new members; in the naming of 150 delegates to the Medical Society of the State of Pennsylvania; and in the election of the following officers: President, Dr. Thomas H. Fenton; vice-presidents, Drs. Francis M. Perkins, and J. Chalmers Da Costa; secretary, Dr. Ellwood R. Kirby; assistant secretary, Dr. William S. Ray; treasurer, Dr. Collier L. Bower, and censor, Dr. W. Joseph Hearn. The Society unanimously adopted the following resolutions:

"WHEREAS, Smallpox is continuing to spread among the people of the city; and

"WHEREAS, Sensational newspaper articles minimizing the importance of vaccination have caused a number of people to refuse the vaccination offered by the city physicians; and

"WHEREAS, Of the 977 cases of smallpox admitted to the Municipal Hospital during 1901 there was not a single patient who had been successfully vaccinated within a period of four years, those alluded being almost exclusively unvaccinated persons or adults not vaccinated since infancy; therefore, be it

"Resolved, By the Philadelphia County Medical Society, representing the physicians of the city and county, That this Society deems it necessary to impress upon the community that universal vaccination is the most effective means of stamping out smallpox, and that, although fumigation and disinfection are valuable adjuncts, they can by no possibility do away with the necessity for vaccination since smallpox patients are the most important carriers of infection, and such infection can not be influenced by the disinfection of smallpox. Be it further

"Resolved, That publications which slur the importance of vaccination despite the incontrovertible testimony of 100 years are to be deprecated as contrary to the best interests of the community. Such articles are known to have dissuaded people from vaccination who have subsequently died of smallpox."

# CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL SOCIETY.

*Regular Meeting, held Nov. 12, 1901*

President, Dr. William E. Casselberry, in the Chair.

## Secondary Hemorrhage Following Tonsillotomy.

Dr. HOMER M. THOMAS read a paper on the above subject. He said: I never perform a tonsillotomy with the tonsillotome without grave forebodings of secondary hemorrhage. When I began professional work nineteen years ago, this fear was not in my mind, and for several years I had no cases in which there was more than slight hemorrhage following the excision of the tonsils with the tonsillotome. Later on, however, and at very unexpected intervals, I have had hemorrhage occur in cases where there appeared to be no indications of the possibility of hemorrhage. The case I wish to present to night occurred in my practice recently, and was quite a surprise. The young lady, Miss S., aged 18, had been referred to me for the excision of two hypertrophied tonsils, moderately large, by her family physician. One of the young lady's friends had her tonsils removed with a tonsillotome about six months before, and had suffered from considerable hemorrhage. This so alarmed my patient that she asked me to use every possible precaution to avoid such an occurrence in her case. In view of the circumstances, I was particularly anxious that the operation be a success, and adopted what I considered very great precautions, but they were futile. The right tonsil was removed at about 10 a. m. on Monday with a Matthieu tonsillotome. The line of excision came at about the pillar of the fauces. There was no hemorrhage of any moment, but the young lady was kept under observation for several hours, no hemorrhage occurring. She went home, and on the following Wednesday she returned and the left tonsil was removed. The interval was allowed in order that a firm clot might form in the right tonsil, and prevent hemorrhage. No difficulties were encountered, the excision was easily made, and the patient remained in the office for several hours before returning home. On the following morning, at about five o'clock, I was telephoned that the throat was bleeding severely. I suggested ice and astringents, and supposed that would be the end of the matter. The bleeding increased, however, and about 10 that morning I went to the patient's residence, expecting to find a secondary hemorrhage from the tonsil operated on the day before. On my arrival I was surprised to find a severe hemorrhage from the right tonsil, about 65 or 70 hours after the excision of the tonsil. The clot, which had become detached, was saved, and I found it ragged and undergoing some disintegration. A local application of tannic and gallic acids temporarily checked the bleeding, but the clot was expelled by coughing, and the bleeding recurred. I then applied a saturated solution of ferropyrin, which temporarily controlled the bleeding. The spurting was synchronous with the heart action. I was unable, however, to control the hemorrhage with any styptic, and I finally resorted to the use of the Lentz mouth-gag, leaving it in position for two hours, when the hemorrhage ceased.

Dr. HENRY GRADLE, in discussion said: I can report an instance of secondary hemorrhage following a tonsillotomy made with the snare. A gentleman about 30, perfectly healthy, had hypertrophic conditions in the pharynx and nose, attended with considerable deafness and moderately large tonsils. Both tonsils were cut off smoothly with a hot snare. On the third night following, he came to me bleeding very freely, not an arterial hemorrhage, but a venous oozing. It continued for a number of hours, and was finally controlled by antipyrin and tannin. Hemorrhage again set in the next day, but was very trifling. The bleeding was due to an ulcerated condition.

Dr. OTTO T. FREER—It seems to me that primary or secondary hemorrhage is apt to follow any method of operation for removal of the tonsils. I recall a serious case of secondary tonsillar hemorrhage succeeding excision of a buried tonsil by cautery dissection. When I saw the case the bleeding had lasted from 2 a. m. to 10 a. m. and attempts had been made to check it with iron perchlorid. Packing of the recess created by the tonsillotomy between the pillars with cotton and tannic acid powder stopped the bleeding. The exsanguinated

state of the patient had much to do with the cessation of hemorrhage, and I think that this stops often of its own accord when syncope is imminent and the last remedy applied is supposed to have done the work performed by the lowered blood pressure. Where tonsillotomy is done through the substance of the tonsil, hemorrhage is more apt to occur than if the tonsil be removed from its base, as the tonsillar substance, especially if hard and fibrous, prevents retraction of the arteries, while this takes place normally in the cellular tissue behind the tonsil if that structure be completely removed. It is for this reason that I advocate Ingals' operation for *écrasement* of the tonsil as the Ingals' tonsil forceps lifts it from its bed after separation of the anterior pillar with a blunt hook and the steel wire snare passes under the tonsil, enucleating it completely. In all the many tonsilleotomies done through many years in the clinics at Rush Medical College there has never occurred a serious hemorrhage after the use of the cold wire snare employed after the method of Ingals. I admit that this does not prove that the method is faultless as regards danger of hemorrhage, as bleeding of a severe nature very rarely occurs where the tonsils are removed in childhood and the snare operation is practically limited to children in our clinics; still I think the method deserves some credit for the entire absence of serious hemorrhage in so many years. For controlling tonsillar hemorrhage I have found among the simpler means powdered tannic acid the best, packed well into the tonsillar recess with a cotton plug if this can be done.

Dr. WILLIAM L. BALLENGER—Dr. Freer has just referred to the use of the cold steel wire snare as a good method for removing tonsils. I have used this method a number of times within the last year, but the results were so bad in a few instances that I do not believe that it is the best method of procedure in all cases. I have had three violent inflammatory reactions following the use of the cold steel wire snare. I had one patient who was laid up for nearly two weeks on account of the violent reaction and infection. That may have been my fault and not the fault of the snare, although the usual precautions were taken before and after operating.

I have also had severe hemorrhages with this method, although none of them were secondary. I was led to use it in the belief that a bloodless operation would result. I have used Peter's snare, a powerful instrument, and have had considerable hemorrhage follow its use. Another difficulty is the breaking of the wire. Only last week I had to put in four wires to remove one tonsil; rather an embarrassing procedure. This, however, is the fault of the instrument and can be remedied. As Dr. Casselberry has so well said, there is no operation on the tonsils which is not at times attended or followed by hemorrhage. This is especially true of adult cases in whom the tonsils have become hyperplastic.

Dr. J. HOLLINGER—I have for several years used the method of Killian, as described in the *Archiv f. Laryngologie* a few years ago. The tonsils which always make trouble are those having very large and deep crypts. Killian places a broad hook in the angle of the mouth opposite the tonsils to be examined. He then examines the tonsil with a strabismus hook. He enters from the hilus of the tonsil down into the crypts, looking for the deepest crypts as they are most liable to cause trouble. He then enters the crypts with a bent knife, and slits them open. The crypts are then painted with hydrochloric acid, and they remain open, the tonsil shrinking. The advantages are manifold. I never have seen a secondary hemorrhage. All the cases I have treated in that way got well quick without any trouble. In cutting the tonsil with a tonsillotome, it is possible that you do not cut the whole depth of the crypt, and leave a pocket. When the wound heals the contracting scar tissue closes that little pocket, and there is a worse condition than before. The hilus of the tonsil is that part where all the crypts open. It is between the upper and middle third of the tonsil, quite high up.

Dr. NORVAL H. PIERCE—I have used Killian's method, and had very severe hemorrhage follow. A very healthy gentleman came to me with an embedded tonsil. I explored the supratonsillar fossa, and found a very deep crypt running apparently posterior to the tonsil. I slit it up and painted it

with nitrate of silver. About six hours afterward I was called to my patient's house. I found him nearly exsanguinated. He was bleeding profusely from the cut I had made. I dressed the wound with cotton and ferropyrin—the powder not a solution. A pledget of cotton was rubbed into the powder and then packed in the bleeding cavity.

**DR. J. HOLINGER**—The superior fossa does not belong to the tonsil. Its walls are not tonsillar tissue. It is a pouch that stays open from embryonal life in about 20 to 30 per cent. of the people. If it makes trouble it must be cauterized. If it is attacked with the knife you can not avoid cutting the palatal artery.

**DR. WILLIAM E. CASSELBERRY**—I have observed no less than half a dozen cases of serious hemorrhage following tonsillectomy in adults, and have also had it happen once in childhood. It has happened after all the methods, but most frequently after the use of the tonsillotome. I have had it occur after the galvanocautery and the cold wire snare. Of late years I have adopted largely with adults the fragmental method as a guard against hemorrhage, not that bleeding does not occur after the removal of small pieces of tonsillar tissue at a time, but one is better able to cope with it by prompt cauterization when the cut surface is small. I have, however, had two copious bleedings after the removal of comparatively small fragments, not larger than one-quarter of a moderately hypertrophied tonsil. In one of these cases, it occurred with the last of eight fragments of the two tonsils removed at intervals of a few days, the cut which bled being low down in the pharynx. It was stopped by cauterization of a small spurting vessel. In the other case it was also the last fragment, but the cut was located high up in the velar tonsil and the bleeding was stopped by digital compression. I believe these hemorrhages are liable to occur, no matter what method we adopt, and therefore I am chiefly interested in the measures to be taken to control hemorrhage promptly when it does occur. I believe that a hemorrhage which will be checked by tannic acid, ice ferripyrin, and other preparations of iron, would stop itself spontaneously. I do not favor loss of time in the use of these materials in really serious cases, because my experience indicates that an arterial hemorrhage or a copious venous hemorrhage, capable of exsanguinating the patient, will not be controlled by any chemical astringent. In the case mentioned by Dr. Pierce, where he packed a small cavity with cotton, saturated with ferropyrin, a good result was obtained, but it was undoubtedly the pressure secured rather than the astringent which so promptly checked the bleeding. I have found that the best way is to sponge the throat clear of clotted blood, even at the expense of momentarily increasing the hemorrhage, and to look for the bleeding point, just as one would in hemorrhage from an ordinary surface wound. If one does not find a spurting artery one at least ascertains that it is not an artery that is bleeding, but a general venous ooze, which information is of value in the selection of subsequent means of treatment. In the majority of cases of serious hemorrhage, however, you will find a vessel which has a slight spurt. In most but not all of my own cases I have been able by careful swabbing to cauterize that bleeding point with the galvano-cautery. This apparatus, unfortunately, is not always at hand; also the bleeding may be so copious that without skilled assistance it would be impossible to carry out this method. If there is a cavity or deep sulcus between the faucial pillars that will retain gauze, one would of course pack it, but this favorable condition is usually absent. The next expedient is pressure, and I believe this method is almost universally available, and if resorted to promptly would gain the desired end quickly. To exert pressure one always has at hand his forefinger and thumb, if not one of the various tonsillar pressure hemostats. In one of my cases, after two efforts at cauterization while still in the office, and a third effort at the hospital late in the evening had failed, I applied a Störk's tonsil pressure hemostat, which worked perfectly. In the absence of the hemostat one must use the thumb and forefinger, but it is not always necessary to maintain pressure for a great length of time. In the majority of cases one-half hour at the most would be likely to suffice.

Gauze wrapped around the finger is an aid, and upon this may be placed any desired astringent. I adopted this method in the case above mentioned, in which hemorrhage occurred after the abscission of the velar fragment of a tonsil, and the bleeding which had resisted other methods for two hours ceased after ten minutes' digital pressure. I have had no experience with catching up the bleeding vessel by forceps or ligating the stump or suturing together the faucial pillars. The patient is usually so panic-stricken that complicated methods could not be accomplished without a general anesthetic. One can conceive that a general anesthetic might be necessary to control the patient in order to carry out any method, and this might be especially true of children. I recall only one case of my own in a child, a dispensary patient aged 10 years, in whom secondary hemorrhage occurred eight hours after the operation, and continued till syncope ensued, when the bleeding ceased.

#### A Case of Latent Frontal Sinusitis.

**DR. GEORGE E. SHAMBAUGH**—This woman's nasal trouble dates back 12 years, when following an attack of typhoid fever she began to have a purulent discharge from the right side of the nose, which has continued ever since. Seven years ago she had polyps removed from the right nares. I saw her for the first time two years ago, when she complained of difficulty in breathing through her nose and of a bitter tasting discharge into her throat. Her throat felt dry and sore and she suffered almost continuously from severe frontal headaches, limited chiefly to the right side. She said she suffered frequently from chills and fever and was quite unfitted for any physical or mental exertion. On examination the left side of the nose was found to be normal. The right naris was completely filled with polyps. The pharynx was the seat of a dry pharyngitis. Percussion over the frontal sinuses elicited marked tenderness on the right side. The polyps were removed and with them the anterior end of the middle turbinate body. With the middle meatus thus freely opened, I succeeded in irrigating the maxillary frontal and sphenoidal sinuses by introducing soft silver canulae through their normal openings. From each of the three sinuses a considerable quantity of fetid pus was washed out. I saw the patient for several months, and during that time irrigated all three of the sinuses a number of times with a marked relief in the subjective symptoms and some decrease in the amount of the discharge.

I did not see the patient again until this fall, when a marked change in her condition was noted. She has completely recovered from her severe headaches; the sensation of dryness and soreness in her throat has disappeared; the discharge from her nose has almost ceased and is noticeable only for a short time in the morning after rising. I found the right side of the nose open and no recurrence of polyps. The sphenoidal sinus, the opening into which could plainly be seen, was clean and dry. Irrigation of the antrum brought out a clump of thick, fetid pus. Irrigation of the frontal sinus washed out a similar but smaller quantity of thick pus. Since then I have washed out the frontal sinus six or eight times.

**DR. OTTO T. FREER**—I would like to ask whether the opening in the frontal sinus was in the hiatus semilunaris, or in front of it. Killian says that the opening may be behind the process unciniformis or in front of this, beneath the end of the middle turbinate bone. In the latter case the opening is very short, points directly under the middle turbinate body, and is easy of access.

**DR. WILLIAM E. CASSELBERRY**—I would ask Dr. Shambaugh what the condition was and is, under transillumination; also, whether in washing out the sinus at times when he says he gets no pus, how much pressure he uses; inasmuch as oftentimes when there is but little pus it adheres to the wall of the cavity, and it takes considerable pressure to wash it off. This is of diagnostic importance, as it indicates the degree to which the case has become latent, or whether it is actually a full recovery.

**DR. SHAMBAUGH**, in reply—The opening into the frontal sinus was through the ordinary passages, the infundibulum.

The usual opening for the atypical passage is in front and a little to the median side of the hiatus semilunaris. In regard to transillumination, when I first saw the case I thought I observed a deeper shadow over the right frontal sinus. During the last two months I have repeatedly tried the transillumination test without being able to detect any difference in the two sides. As to the amount of pressure used in irrigation, I made use of a fountain syringe, which I elevated about five feet above the patient's head. The cannula used had a large opening and the water always flowed freely into the sinus.

Dr. T. MELVILLE HAROLD presented a case with "Fracture of the Septum, with an Unusual Complication."

#### Aneurysm of the Arch of the Aorta.

Dr. JAMES T. CAMPBELL presented a case. The patient is aged 75 years, prior to his present complaint, always has enjoyed good health. For 30 years he was in the employ of the L. C. R. R., superintending the construction of water-towers. This kept him out of doors in all kinds of weather, and he had at times heavy lifting and straining to do. Occasional attacks of lumbago is the only disease from which he has suffered. Of late, however, he has had dyspeptic symptoms with constipation. Eighteen months ago, while engaged in work about his barn, he contracted "a cold," had acute coryza and hoarseness. The hoarseness persisting brought him to me. He has a slight inspiratory stridor. The left pupil is dilated, but responds to light. The arteries are cord-like, the radial pulse on the right has a greater volume than that of the left side. The left common carotid has a much greater diameter than it had six months ago. Tracheal tugging was well marked when he first came under observation, but it is now less pronounced. The left vocal cord is in the endavertic position; the left arytenoid cartilage is on a plane anterior to that of its fellow. In eating and drinking (cold water more particularly) he has some difficulty in swallowing. The particles seem to stop at a point back of the upper portion of the sternum and occasion cough. The cough is dry, with no expectoration. On physical examination no unusual impulse is transmitted to the chest wall. On percussion, the heart dulness extends beyond the normal, upward and to the left. On auscultation no bruit can be heard. By the fluoroscope the uniform dilatation of the artery can be very clearly seen, involving the transverse and beginning of the descending aorta. The absence of bruit is, I think, accounted for by the fact that the arterial coats have expanded uniformly, and that there is no special resistance to the blood current.

Dr. Campbell read also a paper on "Ulceration of the Tongue Associated with Pulmonary and Laryngeal Tuberculosis."

Dr. OTTO J. STEIN read a paper on "A Case of Laryngeal Disease."

#### NEW YORK OBSTETRICAL SOCIETY.

*Stated Meeting, held Jan. 14, 1902.*

The President, Dr. Malcolm McLean, in the Chair.

#### Gonorrheal Pyosalpinx Resembling Tubal Pregnancy.

Dr. HERMAN J. BOLDE—At the last meeting of the Society Dr. Coe narrated the history of a patient with gonorrheal pyosalpinx, whom he supposed to have extra-uterine pregnancy. I remarked, at the time, that I, too, had seen women giving histories resembling those we are likely to elicit in instances of ectopic gestation, but they were found to be afflicted with suppurative pelvic disease. The patient from whom this specimen was removed gave the following history:

J. C., aged 34 years, was married 14 years. She had two children; the last two years ago. Menstruation began at 16 and has always been regular when not pregnant. The flow has always been from two to three days' duration, the blood being normal in color. The last menstrual period occurred on December 14, but was only of one day's duration, very scanty, and the blood exceedingly pale. Following the cessation of the flow the patient began to have pains in the left inguinal region, which were described as "labor-like" pains, with exacerbations. The pain at times was so severe that she was compelled to go to

bed and send for her physician. Medicine and hot water bags gave temporary relief; she had no appetite; nausea after eating; constipation. The uterus was somewhat softer and larger than normal. On the left side, a little above the vaginal vault, a thick sausage-shaped mass was felt, soft in consistency and very painful to touch. A small part of the tubal enlargement extended behind the uterus, as though from gravity the distended tube sagged toward the cul-de-sac. The examination being quite painful and nothing indicating trouble being found on the floor of the pelvis to the right of the uterus, a more careful palpation was not attempted at this time. The breasts showed no changes indicating pregnancy. The diagnosis of probable unruptured tubal gestation on the left side was made and the patient was placed in the hospital for observation, so that should the probable diagnosis be decided a positive diagnosis from the result of observation, operation could be undertaken without delay. Four days later, on examination, the previously described tubal tumor was found to be somewhat larger than at the former examination, and both breasts upon pressure gave exit to secretion. This change in the breasts was so marked that an error in diagnosis was not considered likely. A tubal tumor was also found on the right side, but much higher in the pelvis; the exact outlines were not mapped out, because of the danger of causing rupture by brusque examination. The presence of the second tubal distension caused some doubt as to the correctness of the previous diagnosis. The question was between bilateral pyosalpinx and a pyosalpinx on the right side and tubal gestation on the left. Bilateral tubal gestation was not thought of, because of the absence of symptoms pointing to such trouble on the right side. My hesitation to make a positive diagnosis under the circumstances was due to previous experience with patients giving histories such as we are likely to get in tubal gestation, and having a swelling in the pelvis, who upon operation were found to have pus instead of embryo in the swelling felt. Abdominal section in our patient revealed bilateral pyosalpinx. The adhesions of the adnexa to the surrounding structures were extensive and firm. The left tube was enucleated without rupture. The right tube was more distended than the left; the cause of its non-descension into the pelvis was found to be due to intimate adhesions with the small intestines, so firm that the bowel was injured during the separation of the tube. While attempting to separate the ovary from the right oviduct with a view of saving a part of the gland to preserve the function of menstruation rupture took place. On examination the pus showed the presence of gonococci. The husband upon interrogation denied that he had had gonorrhea except one time, between fifteen and twenty years previously. At times, he admitted, the urethral orifice was agglutinated on arising mornings. Considering the history which was given by the patient, in connection with the condition found, the truthfulness of but one attack of gonorrhea fifteen or twenty years ago is, in my opinion, doubtful. Were it true the case would, in my experience, be unique. I would be grateful to hear other opinions, because I consider this a very important question, and it might cause a change of opinion as to gonorrhea in connection with conception. Another interesting feature is the absence of symptoms from the larger right pyosalpinx, with the presence of such intense symptoms from the left pyosalpinx.

#### Inflammatory Growth of Cecum and Ascending Colon Necessitating Resection of Bowel—Recovery.

Dr. HIRAM N. VINEBERG—Mrs. J. S., aged 27 years, had a large ventral hernia following an abdominal hysterectomy performed by me in April, 1898, for acute puerperal sepsis, in which the uterus was studded with abscesses varying in size from a pea to an almond. The abdominal wound was left in great part open so as to admit extensive packing with iodoform gauze; hence the subsequent hernia. The woman was desirous of having her hernia operated on, which I accordingly did on April 15, 1901, at St. Mark's Hospital. There was an extensive adhesion of the omentum to the scar, making the operation rather tedious and of considerable duration. The long abdominal wound healed by primary intention excepting an area about an inch at the upper angle where a sero-

sanguinous discharge took place, opening the wound down to the peritoneum for the aforesaid distance (about an inch). To shorten her stay in the hospital and to prevent a possible occurrence of a small hernial protrusion at this point, I freshened the edges of the wound and sutured it with chromicized catgut, leaving the skin unsutured. The union proceeded normally and the patient was allowed to get up a week later. A few days before getting up, during the absence of the nurse, she had a desire to urinate and reached over the side of her bed for the urinal which was standing on the floor underneath the bed. While doing so she felt something give way, she said, in the right side of the abdomen and she was seized with a sharp pain in that region. The next day, when I saw her, I could palpate an elongated mass about the size of the index finger at the outer border of the right rectus muscle and just below the line of the umbilicus. This mass seemed rather superficial and was quite tender. There was slight temperature, 100 F. She left the hospital May 15 and made very little complaint of the pain in the right side of her abdomen. She was up and about until May 27, when the pain in her side became severe. She felt feverish and vomited a couple of times. She took to her bed and I saw her on May 30, three days later. She then had a temperature of 102 and a pulse of 106. There was no abdominal distension. She had had daily movements of the bowels. On palpation a mass about the size of a closed fist was felt at the outer border of the right rectus muscle. It was rather ill-defined, seemed fixed, and appeared to be immediately beneath the abdominal wall. One of two conditions occurred to me: 1, an appendicitis with a purulent exudate in a somewhat abnormal position; or 2, a gauze compress which inadvertently had been left within the abdomen during the operation for the hernia. On May 30 I cut down upon the mass and found the muscles infiltrated and edematous. Just before opening the peritoneal cavity some dark grumous material appeared in the wound. This was mopped out and the peritoneum carefully opened. I now found a mass about the size of the closed fist, giving the impression of a sarcomatous growth involving the cecum and ascending colon. I resected about eight inches of the gut, going about an inch above and about an inch below the growth. The two ends of the bowel were united by a Murphy button. The patient had a rather stormy convalescence, but ultimately made a good recovery, passing the button on the 19th day after the operation. She has remained perfectly well since. The excised growth seemed to spring from the peritoneal covering of the intestine, was quite friable and could be easily broken off with the fingers. Dr. F. S. Mandelbaum, pathologist to Mt. Sinai Hospital, made a thorough microscopic examination of it and pronounced it to be of an inflammatory nature.

The explanation of the development of this inflammatory growth is not easy. Two probabilities occur to me: 1. A traumatism was inflicted to the rectus muscle in the act of reaching over the side of the bed to the floor. This excited an inflammatory process which extended by contiguity to the peritoneum and underlying intestines. 2. The secondary suture excited a low grade of inflammation which extended in the same way. The following facts are in favor of the first assumption: The sudden onset of the pain following the aforesaid act; the appearance of the mass shortly afterwards, decidedly appreciable when I saw her twenty-four hours later; the site of the original swelling, fully two inches external from the line of sutures and at the outer border of the right rectus muscle.

#### Early Recurrence of Carcinoma in Vaginal Scar Following Abdominal Hysterectomy for Adeno-Carcinoma of Fundus Uteri.

DR. HIRAM N. VINEBERG—The following case is of interest in showing how unfavorable the prognosis may prove to be in the most favorable form of carcinoma of the uterus even when operated upon at a very early date. Mrs. S., about 61 years, widow for 7 years, mother of 2 children. The menopause was established 12 years ago. While in Germany last summer and in apparently good health she was suddenly seized with uterine hemorrhage. She immediately went to Strasburg to consult Prof. Freund. On Sept. 27, 1900, two weeks after the

first appearance of the hemorrhage, an abdominal hysterectomy was performed by Prof. Freund. The extirpated uterus showed a fibroid growth the size of an English walnut in the uterine wall on the left side near the os internum. At the entrance of the right tube into the uterus the mucosa showed a small area of carcinomatous degeneration. The patient made a rapid and good recovery from the operation, the abdominal wound healing throughout by primary union, although a fairly-sized hernia developed at the lower end of the wound shortly afterwards. Three months after the hysterectomy, on Dec. 29, 1900, she consulted me on account of a vaginal bloody discharge which had made its appearance two weeks before. The amount of blood lost was small at first, but latterly had grown quite profuse and she passed several large clots. Her general appearance was quite good though she complained of some weakness.

On vaginal examination a friable mass, the size of the end of one's thumb, was found occupying the scar in the vagina. It bled very freely on being touched. To the left of this the tissues were found pretty extensively infiltrated. The inguinal glands were not found to be enlarged and no infiltration existed in the abdominal scar. On Jan. 2, 1901, I excised with scissors, curette and Paquelin cautery the mass in the vaginal scar and as much of the infiltrated tissues as was feasible. The removed tissues were kindly examined by Dr. F. S. Mandelbaum, pathologist of Mt. Sinai Hospital, who pronounced them to consist of epithelial carcinoma. The patient, after this, had no further hemorrhage and seemed to improve in her general health. But in the early part of May she showed marked signs of cachexia and died on May 30, eight months after the original operation.

#### Long Mucous Polyp Attached in the Upper Portion of the Uterus in the Horn Protruding at the Introitus Vaginae.

DR. MALCOLM McLEAN—Mrs. C., aged 52, married, a multipara, has had "dragging pains in the back" with frequent sensations of "bearing down" for the past three or four years. There has been a feeling of obstruction in evacuation of the bowels accompanied by a sensation of dragging in the vagina "as though all the organs were coming out." During all this time there has been an exhibition of irregular metrorrhagia, with irritating watery discharges in the intervals. The patient has been very anemic although she is of excellent build and has healthy organs apparently throughout the rest of the body. Examination showed a uterus slightly enlarged by an interstitial fibroid. Protruding into the vagina to the introitus was found a long polypoid growth, soft and traversed by cell-like cavities. It was attached by a rather narrow base (one-half inch) to the left horn of the fundus uteri. Under ether anesthesia it was drawn down and easily detached by dissecting it off with the finger. It measured five and a half inches in length and two and one-quarter inches in diameter. The patient is recovering promptly.

#### Dudley's Operation for the Relief of Severe Cases of Recto-Vaginal Fistula.

DR. A. PALMER DUDLEY—I devised this operation while delivering my course of lectures at Dartmouth Medical College last year. I have presumed to designate it as "Dudley's Operation for the Relief of Severe Cases of Recto-Vaginal Fistula," because, so far as I am able to learn, in looking over the record of such cases, it is original with myself and rather a unique procedure; nevertheless, it was successful and, in my judgment, will in the future receive recognition from the profession, and take its place as a surgical relief for such a condition.

A short description of the case and the method of procedure for relief would be the most concise manner in which I can present my claim for originality for the operation. The patient operated on by this method was 47 years of age, married and the mother of three children. She was admitted to the Mary Hitchcock Hospital July 23, 1901, suffering from a combination of pelvic diseases, of which may be mentioned, hemorrhoids, laceration of the perineum, recto-vaginal fistula, laceration of the cervix, and retro-displacement. The major condition was

recto vaginal fistula, through which fecal matter and gas constantly escaped, which had been operated upon twice before, without successful result. She was a woman without means, occupying a free bed in the hospital, so I determined to do all necessary work for her, provided she stood the anesthetic well. Each and every member of this Society is, or should be, perfectly familiar with the operative methods of procedure for all forms of fistula as practiced by Sims, Emmet, Bozeman and their followers down to the present time, and it would be out of place for me to call attention to the different methods and peculiarities of each operator. Instantly upon examination of this case, I recognized the possibility of a third failure unless I could by some means treat the rectal mucous membrane, and in some manner whereby it would be impossible for a leakage of gas and fecal matter to take place, in case the vaginal site of the wound did not heal by primary union, and as the patient was suffering from hemorrhoids which required removal, I determined upon the following plan:

The patient was placed in the Sims's position, the quadrivalve speculum was introduced into the bowel, and the sphincter am thoroughly but carefully divided. I then made Whitehead's operation for hemorrhoids, going right around the entire anus, just through the mucous membrane. I then dissected the mucous membrane of the rectum from the attachment to the sphincters, and continued the dissection, separating the mucous membrane of the rectum from its attachments to a level with the upper edge of the opening in the bowel, carefully separating the mucous membrane of the rectum from around the edge of the fistula. I then continued the dissection on sufficiently far to allow me to draw the rectal mucous membrane, including the fistulous opening, down to the anus. The mucous membrane of the anus was so dissected out, was then cut away including the hemorrhoidal vessels. The mucous membrane of the rectum was then sewn to the skin of the anus around the entire circumference of the latter, as in Whitehead's operation for hemorrhoids. This procedure, of course, did away with the fistulous opening in the rectum. The patient was then turned upon the back, the uterus curetted for fungous growth, the fistulous opening through the vaginal coats denuded, and sewed up, simply as a superficial wound in the vagina with catgut. The perineum was then restored by my own method of procedure, using only catgut as a suture. A small abdominal incision was then made, adhesions about the uterine appendages broken up, and the uterus brought forward and fastened by ventro-suspension. The patient went to bed in good condition. Each one of the wounds healed by primary union, and the patient left the hospital just four weeks after the operation, with good control of the sphincter ani, the fistula perfectly healed, and the uterus in good suspension. I want to draw attention to one point in this operation, and the future application of it in cases of accidental fistula high up in the vaginal vault, as a result of hysterectomy. In my judgment in cases of high fistula, it would not be necessary to resect the bowel to a level of the fistula, but only such portion of the bowel as would be sufficient to change the position of the rectal opening, with that of the vaginal, so as to lap each fistulous membrane against unbroken structures and then sewing the parts carefully together with whatever sutures you deem best suited to the occasion.

#### DENVER AND ARAPAHOE MEDICAL SOCIETY.

*Regular Meeting, held Jan. 14, 1902.*

The President, Dr. H. G. Wetherill, in the Chair.

#### Consumption Contracted in Colorado and Methods to Restrict Its Spread.

Dr. S. G. BONNEY holds the opinion that the infection of tuberculosis is extremely slow and incremental in character, the contagion constituting a source of danger to such alone as are especially predisposed, and only after prolonged exposure or repeated infection. Tuberculosis developing in Colorado should not be ascribed, therefore, as resulting from intimate association with pulmonary invalids after the manner of certain contagious diseases. As a direct causal factor in the development

of the disease in Colorado should be considered the unfavorable occupation of a considerable class of her people, namely, the miners. Absence of sunshine, inhalation of an atmosphere vitiated by dampness, dust and smoke, climbing of mountains and ladders in high altitudes, and carrying of heavy burdens can not fail to exert a deleterious influence. Another factor is the strong inherited susceptibility of her youthful population born of tuberculous parents. The question whether consumption developed in Colorado is increasing from year to year, is of momentous importance. The State must secure adequate protection for her communities without unnecessary infringement upon the rights and privileges of her consumptives. The medical profession must also assume an enormous responsibility in its advisory capacity. It is natural that much interest would attach to the report of the committee upon tuberculosis appointed a year and a half ago by the State Society, which was made public at the last annual meeting. The report states that the total tubercular death-rate for the 16 months during which the statistics were collected, is 13.32 per cent. This happens to be the same proportion as was published by the Denver Health Department in 1894. Besides, the increase in population has not been taken into account. Nearly one-fourth of all cases developed in Colorado were children under 5 years of age. These deaths should not be included as instances of indigenous tuberculosis. Out of a total of 224 cases, one-fifth occurred in miners. The location of the indigenous cases by counties is interesting. El Paso County, containing relatively more consumptives than any other county in the state, had only six cases. Gilpin County, in which consumptives are but few, offers a percentage nearly three times as large. The explanation is that the inhabitants of El Paso enjoy the privileges of sanitation, but the inhabitants of Gilpin County are mostly composed of miners who devote less attention to hygienic laws. Furthermore, there is an entire absence of proof that these cases were actually contracted in Colorado. Such an attitude of the committee implies the non-acceptance of the theory of latent tubercular process. The committee reports that numerous experiments with animals have shown that animals may be as readily inoculated with the tubercle bacilli at this altitude as at a lower one, yet one fails to appreciate the practical significance of the inquiry. He does not understand how any reasonable interpretation of the official data justifies the implied, not directly expressed, conclusion of the committee of a rapid and an alarming increase of tuberculosis in Colorado. He has seen 16 cases during a period of ten years out of a series of 1200 reported cases of consumption who were kept under rather continuous observation. Two were old miners, one a stone-cutter with chronic Bright's disease, one a layer of carpets and one employed in a steam laundry. The etiological factor in these 5 cases is evident. Two have developed the disease six months after arrival; it is uncertain, therefore, whether the disease originated in Colorado. In 3 there are distinct histories of exposure. The remaining examples of tuberculosis developed in Colorado, for which no explanation could be found. He protests against such incendiary public utterances from medical men in Colorado, as have given the impression that the future of our communities are being seriously endangered from imported cases. The promulgation of such views are not warranted by facts. He advocates the following measures for the restriction of tuberculosis: 1. Compulsory notification and registration. 2. The education of the consumptive himself, in the rigid observance of sanitary precautions. 3. State sanatorium for the poor. 4. Segregation hospitals for the hopeless and impoverished. 5. Periodic disinfection of apartments occupied by the sick. 6. Prohibition of expectoration wherever people walk. 7. Public attention should be drawn to proper mode of living, occupation, etc. 8. For creation of societies for the study and prevention of tuberculosis. 9. Government and municipal supervision of the construction of public buildings, tenement houses, factories, etc.

DR. HENRY SEWALL said that the outside world is bound to misunderstand us. The question is: Is tuberculosis developed in Colorado or not? The facts warrant a positive assertion. What is the probable progress of the disease during the next

century? Since no one denies the existence of indigenous tuberculosis in Colorado, and since such cases developed only during the last two decades, and now two persons out of every 10,000 die of it, it is more than probable that the disease is on the increase.

DR. E. F. WAXHAM agrees with Dr. Sewall. While we should teach that tuberculosis is a communicable disease, we should also teach that it can be restricted.

DR. CARROLL EDSON contends that half of the cases reported by the committee has not been verified by bacteriologic examination.

DR. O. J. PFEIFFER has not seen a single case of indigenous tuberculosis in Colorado during all the years of his practice.

DR. S. A. FISK said that his experience is not in accord with the conclusion of the committee of the State Society.

DR. G. E. TYLER said that those who speak disparagingly of the work of the committee have probably not read the report in the original. All the committee claimed was summarized as follows: That tuberculosis is indigenous to the State; that it was not formerly indigenous, but has become so through infection from imported cases; and that plans to prevent the further spread of this disease be devised and put in execution at the earliest possible moment.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, XI.

(Continued from page 272.)

#### Methods of Administration.

Medicines for general effect may be administered in one of the following ways:

1. Hypodermically.
2. Endermically.
3. As a liniment.
4. As an ointment.
5. In the form of a suppository per vaginam or rectum.
6. By the respiratory tract.
7. Per os.

#### Hypodermic Medication.

The advantages of hypodermic medication are that certain results may be expected from the dose given, because it enters directly into the circulation and consequently does not undergo any change or decomposition which might take place if given by the stomach. Physiological results are obtained much quicker than by any other method of medication. It is the best means of administration when the stomach is not capable of promoting proper absorption. In emergency cases where rapid stimulation is imperative this method should be employed. In cases of acute pleurisy, for illustration, or an attack of gallstones, or perhaps an acute attack of appendicitis, when medicines can not be borne by the stomach, the pain may be relieved by hypodermic injections of morphine or codein. The possible consequences of this method, however, can not too constantly be borne in mind, namely: The dangers of the patient contracting the drug habit. A large percentage of these habitués places the blame of their downfall upon the physician. That the use of the hypodermic needle in the hands of the physician has been abused, in a great many instances, there can be no doubt. The relief of pain, the promotion of sleep, and the quieting of nervous symptoms can be obtained by other methods in the vast majority of cases if the physician would devote a little more time to the study of his patient and the accompanying symptoms.

However, when the conditions demand hypodermic medication, a proper site should be selected for the injection, the most suitable localities being the outer aspects of the arms and thighs, the abdominal wall, between the scapulae and in the

calves of the legs. On the thigh, just anterior to the greater trochanter, it is said that there is an area two inches square over which a hypodermic needle can not be felt on account of the comparative absence of nerve filaments.

The experience of recent years has introduced methods of treatment which sometimes demand large quantities of fluid to be introduced beneath the skin, such as the introduction of normal salt solutions, to take the place of large quantities of blood lost in an operation; the injection of antitoxins in treatment of the infectious diseases and the introduction of gelatin solutions to check dangerous hemorrhages. When such large quantities are to be given, locations upon the body should be chosen where the skin is loose and the large needle can be easily introduced. The fluid should be allowed to flow as slowly as possible, no difference how great or small the quantity. It is not unusual for sloughing to follow at the site of the injection when it is pushed in too hurriedly, due probably to destruction of the capillaries supplying the parts. It is not necessary to mention the need of absolute cleanliness in preparing the skin for the injection and in rendering the needle thoroughly aseptic, also of certainty that all the air has been excluded from the syringe. Sometimes it is preferable to inject remedies immediately into the deeper tissues in order to reach a certain set of muscles or to produce some local influence upon a large nerve trunk. In cases of progressive muscular atrophy, in its earlier stages, hypodermic, or better parenchymatous, injections of medicines are often recommended. The introduction of a sedative directly into the nerve sheath in severe attacks of sciatica is frequently resorted to.

(To be continued.)

#### Ergotin per Rectum in Metrorrhagia.

According to *Jour. de Med. de Paris*, in cases where ergotin is not well borne by the mouth, it can, after preliminary lavage, be injected per rectum in the following combination:

|                        |         |    |    |
|------------------------|---------|----|----|
| R. Ergotini .....      | 3iiss   | 9  | 50 |
| Acidi salicylici ..... | gr. iii |    | 20 |
| Glycerini .....        | 3v      | 18 | 75 |
| Aq. destil. ....       | 3iiss   | 75 |    |

M. Sig.: Inject one teaspoonful per rectum, first diluting it with three tablespoonfuls of water.

#### Quinin as a Styptic and Antiseptic.

Occasionally the general practitioner is called upon to check hemorrhages which are stubborn to treatment. Marx, as noted in *Med. News*, states that iodoform and its derivatives have so many objections that he has been induced to search for other substitutes. Among these he has tried quinin with great satisfaction. He employs the following combination:

|                                  |          |        |
|----------------------------------|----------|--------|
| R. Quininae hydrochloratis ..... | gr. x-xx | 66-130 |
| Alcoholis .....                  | 3ss      | 1 88   |
| Aq. destil. q. s. ad .....       | 3ii      | 60     |

M. Sig.: Saturate the gauze and apply to bleeding surface.

#### Treatment of Hiccough Due to Gastric Indigestion.

The following combination, as a stomachic and gastric sedative, is recommended in cases of hiccough due to disturbances of the stomach:

|                                   |      |     |    |
|-----------------------------------|------|-----|----|
| R. Sodii bicarb. ....             | 3iv  | 15  | 00 |
| Tinct. nucis vom. ....            | 3i   | 3   | 75 |
| Spts. chloroformi .....           | 3iii | 7   | 50 |
| Tinct. capsici .....              | 3i   | 3   | 75 |
| Tinct. gent. comp. q. s. ad ..... | 3iv  | 120 |    |

M. Sig.: One teaspoonful in water after each meal.

#### Treatment of Laryngismus Stridulus.

The following is recommended by *Merck's Archives* in treatment of laryngismus stridulus occurring in children two years of age or older:

|                             |        |       |
|-----------------------------|--------|-------|
| R. Tinct. belladonnae ..... | m. xii | 75    |
| Chloralis hydratis .....    | gr. xx | 1 30  |
| Potassii bromidi .....      | 3i     | 3 75  |
| Syrupi aurantii .....       | 3iv    | 15 00 |
| Aquae destil. ....          | 3ii    | 60    |

M. Sig.: One teaspoonful every hour until difficult inspiration is relieved.

### Treatment of the Itching of Chilblains.

Dr. J. Cooperider, of Madison, Ind., states that the experience of thirty years has taught him that the best method of treatment of the itching in frost bite is to immerse the foot in water as hot as can be borne and then increase the heat of the water as fast as the patient can bear it, allowing the foot to remain in the water for twenty or thirty minutes. He states that by repeating the foregoing treatment three times twelve hours apart, a cure will be completed.

### Agreeable Methods of Administering Quinin.

Shoemaker recommends the use of the gelatin-coated pill, *cachets de pain* or *coquilles*. The following is regarded by him as an agreeable method in the liquid form:

|                      |        |     |
|----------------------|--------|-----|
| R. Quinine sulphatis | gr. ii | 113 |
| Aeroli citrici       | gr. vi | 38  |
| Syr. aurantii flor.  | .3i    | 375 |

M. Sig.: To be taken at one dose, placed in a wine glass containing three or four grains of sodium bicarbonate in a saturated solution and drunk while effervescing.

### Mercury in Treatment of Diphtheria and Tonsillitis.

Shoemaker also recommends the following prescriptions to relieve the throat symptoms in diphtheria or tonsillitis:

|                                |        |     |
|--------------------------------|--------|-----|
| R. Hydrag. chloridi mitis      | gr. ii | 113 |
| Antimoni et potassii tartratis | gr. i  | 965 |
| Sacchari albi                  | 3ss    | 190 |

M. Siant chartule No. X. Sig.: One powder every hour or two; or:

|                               |       |     |
|-------------------------------|-------|-----|
| R. Hydragryi chloridi corros. | gr. i | 965 |
| Tinct. guaiaci                | .3i   | 30  |
| Glycerini                     | .3ii  | 60  |

M. Sig.: One half to one teaspoonful every two or three hours.

### Treatment of Adenitis in Children.

If there is no visible cause the diathesis should be sought and treatment applied according to such conditions. In the early stage of acute adenitis before suppurative signs are present, cold should be applied to the swollen glands or a compress wet with a solution of formaldehyd, carbolic acid or corrosive sublimate, which quite often arrests the induration and prevents the formation of pus. If suppuration already exists the involved glands should be freely opened and evacuated. In chronic adenitis general tonics according to the causal ailments should be administered. Inunctions of green soap every other or third day should be tried when tuberculosis is suspected and iodipin given internally. The most reliable treatment is the radical extirpation of the glands. —*Mercé's Archives*.

[Iodipin is an iodine addition product of sesame oil. It is a yellowish fluid of oleaginous taste. It can be given to adults in doses ranging from one to two drams of the 10 per cent. strength, three times a day, or in combination with peppermint water, or flavored with oil of peppermint.]

## Medicolegal.

**Not Liable for Medical Services for Non Resident.**—The Supreme Court of Nebraska holds, in the case of Gilligan vs. The Town of Grattan, that a township is not liable for medical services rendered a non-resident pauper, as for example where a person injured on a railroad in one township is brought into the city in another township, where a justice of the peace orders a physician to render professional services to him at the expense of the township. Whether the county would be liable, under the Nebraska statute, the court does not say. But it declares that no county, nor any subdivision thereof, is liable for the support of the poor or medical attendance bestowed thereon unless the legislature has so authorized. And, "poor within the town," it holds, means paupers whose domiciles are in the town.

**Describing Pneumonia as "a Cold."**—In an application for a policy of life insurance the applicant warranted that he had never been seriously ill, and that within two years be-

fore making application he had not been under the care of a physician except "for cold." These statements were by the policy made part of the contract as warranties. Their falsity, the Supreme Court of New Jersey holds, *Finn vs. Metropolitan Life Insurance Company*, annulled the contract. It was shown that within the two years the party had been ill with pneumonia, by which he was confined to his bed, under the care of a physician, for about two weeks. The suggestion that the illness could be truthfully described as "a cold," the court holds, could not be reasonably entertained, and the insurer had a right to expect information more consonant with the fact. The warranty made the validity of the policy dependent on such information being given.

**Imprudently Treated Wound.**—A man was slightly wounded in the leg by the bite of a dog. His daughter obtained from the owner of the dog a small bunch of the latter's hair, and conceived the idea that it would soothe the wound, and cause it to heal. She put this hair on the scratches inflicted by the animal, carrying out the old saw that the hair of the dog is an antidote for the bite. After having put on the hair, she applied a piece of salt meat over the hair. The hair and the salt meat remained on the wound for about a week, at the end of which week erysipelas developed. The application was removed, and a physician sent for. But the man died. The Supreme Court of Louisiana holds, *Martinez vs. Bernhard*, that, in such a case, the owner of the dog could not be held liable for damages, the two physicians who examined the wound testifying that septicemia probably resulting from the imprudent treatment, and not the bite of the dog, was the cause of death.

### Presumptions Where a Person Asks for a Certain Drug.

—The Supreme Court of Iowa says, in the case of *Gibson vs. Torbert*, that it believes the true rule deducible from reason and from authorities is that when a person who has reached the age of discretion, and who is apparently in the possession of his mental faculties, applies to a druggist for a certain drug, he represents to the dealer, by implication, at least, that he knows its properties and uses, and that he is a fit person to whom sale thereof may be made; and that unless there is something connected with the transaction, or something previously known to the seller, indicating that the would-be purchaser can not safely be intrusted with the substance, a sale of the substance called for may be made without explaining its properties or the manner in which it may be safely used or handled, and that, under such circumstances, the seller is not liable in damages for injuries to the purchaser resulting from the improper use or handling of the article, no matter how little knowledge the purchaser may in fact have had of its properties, or of the manner in which it could not be safely used or handled. It appears clear to it that the vendor's legal duty to such a purchaser can go no further than to give him the identical substance he calls for. Nor does it think that it will do to say that a man who may not be able to correctly compose or to correctly spell, or whose writing is poor, is unfit to be intrusted with dangerous substances; for some, at least, of the great inventive geniuses of the world have been deficient in all of these respects.

**Opinion of Patient as to Intent of Physician.**—The principal and vital question in the case of *State vs. Pierce*, the Supreme Court of Minnesota says, was whether the physician charged with the crime of abortion used instruments upon the person of the complaining witness, and gave her medicines, with an intent to bring about a premature delivery, or for the purpose of treating her for a venereal disease; the use of instruments and the giving of medicines being admitted. Against the objections of the physician's counsel, the trial court permitted this witness to express her opinions or conclusions as to the purpose for and intent with which the instruments were used and the medicines furnished. The Supreme Court holds that this was a prejudicial error, for which the verdict of conviction must be set aside. It says that it was the physician's right to have his intent determined from the facts proven, independently of the opinion or conclusion of the woman as to what he might have intended. His intent was to be determined from what was done, and not by what the

woman thought as to his purpose or object when he treated her. The answers given to the questions were not statements of evidentiary facts, but simply opinions and conclusions as to the existence of a vital fact, and they were not relevant thereto. If the complaining witness could be allowed, in aid of conviction, to express an opinion to the effect that the physician intended to produce a miscarriage, she could have been allowed for the same reasons, and on the same grounds, and to facilitate an acquittal, to express an opinion that he simply treated her for gonorrhea. The impropriety of such testimony is very evident. That it strongly tended to prejudice the physician's case in the minds of the jurors is manifest.

**Limitation of Privilege After Death of Patient.**—In the case of the State of Iowa vs. Grimmell, a prosecution for murder in the second degree which it was alleged was the result of an abortion, where a verdict of not guilty was returned, certain testimony of a physician who had been called into the case was excluded as privileged. But the Supreme Court of Iowa disapproves of this ruling. Section 4608 of the Iowa Code provides: "No physician or surgeon \* \* \* who obtains information by reason of his employment \* \* \* shall be allowed, in giving testimony, to disclose any confidential communication properly intrusted to him in his professional capacity, and necessary and proper to enable him to perform the functions of his office according to the usual course of practice. \* \* \* Such prohibition shall not apply to cases where the party in whose favor the same is made waives the rights conferred." The Supreme Court says that even in civil cases it has extended the language of the statute, and expressly held that the prohibition may be waived, either by the testator, or after his death by those who stand for him. And it says that it surely will not do to hold that a statute intended to protect a patient should operate as a shield for one who is charged with murder. Such a construction, while perhaps technically correct, is evidently so foreign to the purpose and object of the Act, and so subversive of public justice, that it ought not to be adopted, except for the most imperative reasons. The safety of the public is the supreme law of the commonwealth, and the Supreme Court says that it does not think the legislature, in passing the act in question, intended it to operate as a barrier to the enforcement of the criminal laws of the state. If the patient were alive, perhaps no one but she could waive the prohibition. But in this case she was dead and unable to speak. If in a civil case her representatives might waive the prohibition, the court sees no good reason for saying that in a criminal one the prohibition is absolute. The purpose of the statute, as has been stated, is to protect the patient, and not to shield one who feloniously takes his life. The authorities, the court adds, uniformly support this position.

1. **Gold Ball Implantation.**—Some five years since Fox devised a method of implanting a glass ball into the orbital cavity where the eyeball has been removed. He finds this somewhat defective; that in about 33 per cent. the method failed and the glass ball was expelled. Even when closing the wound and retaining the ball *in situ* there was still 15 per cent. of expulsion. Eighteen months since he devised the present method, which he recommends. The eyelids are kept apart by the speculum, the conjunctiva is then grasped up and in above the inner canthus, and the tissues pulled out. He then passes a Beer's knife or curved keratome somewhat obliquely and well down through the tissues into the orbit, making the opening large enough to push in a gold ball. He enlarges this with curved scissors, separating the tissues from the cellular tissues around the orbit, affording a large pouch. He uses gold balls of 11, 12, 13 and 14 millimeters in diameter and inserts one through this opening, and holds it in place by what he calls the conformer—a metal shell with a circular opening in which the gold ball fits, corresponding to the cornea of the eye. The eyelids are closed over the conformer, which is left in place twenty-four hours. The results obtained by the method are perfect; no secondary trouble follows; all heal by first intention. The two stitches employed for closing the incision are taken out on the third day.

5. **Hepatic Syphilis.**—Syphilitic affections of the liver occur in a variety of ways; the occurrence of icterus in the course of lues indicates liver involvement, no definite explanation of which has been produced. That the condition is of specific nature is not probable, but upon what transitory changes, or effects of the action of the syphilitic virus, it depends, is wholly conjectural. The passive hyperemia of the liver is not a specific affection, but doubtless it arises in consequence of disease of the heart and arteries, where the poison ordinarily produces alterations leading to circulatory disturbance. There is no uniformity of opinion in regard to ascites, but the predominance is in favor of its being present in syphilitic diseases of the liver, but under certain conditions only. It may be expected in general cirrhosis, and if the portal vessels are pressed upon by gummata, constricted by scars, or obliterated by endophlebitis. In gummatous hepatitis ascites does not appear unless there is concomitant disease of the kidneys or heart, or chronic indurative peritonitis. The syphilitic inflammations are referable directly, perhaps, to the action of the specific virus or poison. Possibly the toxins are derived from the growth of some specific organism. Flexner analyzes the statistics of the Philadelphia Hospital from 1867 to 1901, and finds 88 cases of hepatic syphilis in over 5000 autopsy records. The types of the disease are the interstitial hepatic, gummatous, perihepatic and amyloid. The first made up about one-half of the cases, next to which in frequency came the gummatous form (23); perihepatitis was observed 16 times; amyloid disease 7 times. The so-called syphilitic scars were met with 38 times. It is a question whether they are to be regarded as healed gummata or not. It seems probable that these heal up, and the author reports a case indicating this. The outlook for syphilitic interstitial hepatitis is less favorable than gummatous disease, although if the condition is not advanced it is more favorable than non-syphilitic cirrhosis.

Amyloid disease is also to be considered of serious import and yet it has yielded to treatment. The stage of infection to which hepatic lesions belong has been much discussed, and Flexner says that the profound lesions of hepatic disease will be found in association with symptoms of the tertiary stage; and while it is highly probable that the general cirrhosis appears at that time, the gummatous nodules and amyloid must belong to that period.

**6. Electricity in Renal Disease.**—Rockwell employs a high tension Faradic current, using flexible electrodes over the kidneys and currents almost as strong as can be borne without discomfort; also the static wave current in connection and alternation with the high tension Faradic current. He finds a very decided benefit from these methods, in increasing diuresis by increasing blood pressure in the organs, and in this way it is to some extent at least that its benefits are produced. He combines with the local treatment the older method of general Faradization, which is likewise efficacious but more tedious to the physician and patient.

**7. Congenital Atresia of the Anus.**—The methods of treatment in these cases are described in detail by Wilson, who concludes that the best procedure to be followed in cases of imperforation is: 1. The strictest observation of the anatomic condition present. 2. A study of the condition of the infant, relative both to the urgency which may be necessary to relieve the obstruction and its ability to withstand a second operation.

**8. Syphilis.**—Lydston points out the importance of the general hygienic management, care as to elimination by free ingestion of fluid, by baths, attention to the bowels, etc. In giving iodids he thinks the best course is often to give the daily dose in a large quantity of water and instruct the patient to drink the entire amount, a glassful at a time, at intervals during the twenty-four hours. In this way iodism may often be avoided. Digestive disturbances require attention, and sometimes experiments with the various forms of mercurial salts may be necessary to see which may be best employed. In some cases where the lesions, especially of the mucous membrane, are very resistant and the patient does not tolerate mercury and the iodids, chlorate of potassium, given in 10-gr. doses four times a day largely diluted in water, will be found very beneficial. Tonics, of course, should be employed, arsenic with the mixed treatment is useful not only in preventing iodism but in its general effect on the system. The cardinal principle in the therapy of syphilis is that the physician should remember that he has to deal with three factors: 1. A specific disease to be controlled by specific medication; 2, a distinct individual personality in each patient; 3, the results of anti-specific medication.

**9. Mastoid Surgery.**—Pyle points out that in a number of cases operative methods are not advisable. If everybody was equally skilled in technique and were congestion and granulation essentially operative, we could more cheerfully recommend it. But he says under existing conditions there is not an otologist who would not trust to antiphlogistic remedies until indications were pronounced, rather than submit himself to inexperienced hands. It is wiser to counsel delay and the use of antiphlogistic measures than to encourage hasty operative procedures. The experienced surgeon with clear conception and faultless technique may save life and function, but in the hands of the many the protective and reparative processes of Nature will be abetted more and embarrassed less by rational antiphlogosis.

**11. Artificial Respiration.**—Matas' article is a very elaborate description of the apparatus modified by him for producing artificial respiration, somewhat after the Fell-O Dwyer method, and which consists in a graduated tube which may be adjusted to any quantity of air required. It is provided with a mercurial manometer which indicates the intrapulmonary pressure and is an index to the peripheral resistance that is overcome by the insufflation, and an automatic cut-off which prevents any backward leakage of air, putting the inspiratory inflation of the lungs under the control of the operator. It is

also provided with an air-filter which purifies the air and is arranged with a funnel and tube, which can be used for the administration of chloroform or oxygen, and various canulas and tubes for intubation.

**12. Foot-Wear.**—Sampson gives a statement of the scientific principles which should govern the fitting of foot-wear both for normal and various pathologic conditions. The article is well illustrated.

**13. Sugar-Forming Ferment in Suprarenal Extract.**—In view of the fact that diabetic symptoms develop in cases of suprarenal diseases, and that certain pigmentation anomalies are common to both diabetes and to the former, with the fact that an intimate relation exists between the formation of so-called bile pigments and their pulmonary pathologic pigmentation and the destruction of physiologic sugars, Croftan has been led to investigate the effect of suprarenal extract on the conversion of glycogen. This study seems to show the presence of a diastatic ferment of great power in the suprarenal glands in quantities of nearly as large a percentage as those found in the pancreas, thus justifying the deduction that the suprarenal glands are in some way concerned in the diastatic processes of the animal organism and the conversion of glycogen to sugar. It is impossible at present to decide whether the suprarenals manufacture a diastatic ferment or retain the diastatic ferment formed elsewhere in the body and carried to them in the blood and lymph stream. The effect, however, would be ultimately the same, provided the play of the inhibitory and excitatory symptomatology is correspondingly regulated. He also reports experiments on the production of glycogen following the injection of suprarenal extract in animals which show that it can cause an excretion of dextrose provided the quantity injected is sufficiently large. The effects were transitory in all cases and all the animals recovered. There was some evidence of kidney irritation shown by the presence of albumin, and the appearance of small quantities of bile pigments in the urine and local discoloration near the site of the injections are suggestive. It is desirable, he says, that the suprarenals be examined as closely as possible in all cases of diabetes that come to autopsy, and that this promises a favorable field for investigation.

**14. Obstetric Forceps.**—Abbott speaks in regard to the carelessness of some obstetric physicians in urging patients in labor who have cardiac disease or severe anemia or neurasthenia, to exert themselves unduly and suggests the use of forceps in these cases immediately after the second stage so as to prevent all straining and thus starting up cardiac or tubercular trouble.

**18. Syphilis.**—The various conditions that may give rise to trouble in the diagnosis of syphilis are noticed by White. Syphilis simulates a great many other conditions. He emphasizes the importance of not attributing too much to the presence or absence of primary lesion or the history of same. He thinks that we should have the courage to make the diagnosis of syphilis without regard to social position or moral character for it occurs everywhere. Another fault is insufficient treatment. He tells every patient that he sees for the first time with syphilis that it is a matter of three years' care at the shortest in every case; that the first year is a year of perpetual, continuous, uninterrupted treatment; that the second year may be the same or an interrupted course, according as the first year goes on under observation, and that the third year is a year of observation, but without that year and entire freedom during it from every manifestation of the disease one can not assure the patient that he is well or likely to remain so.

**19. Needless Laparotomies.**—Munro reports eight cases in which he regrets that he was led to operate, though he fears that under the same circumstances he might act in the same way again. The cases were those where apparently laparotomy was justified, but the condition turned out to be of another nature. They were 1 of acute phosphorus poisoning, 1 of hepatic cirrhosis, 2 of acute nephritis, 2 of alcoholism, 1 of obesity, and 1 of supposed pancreatic cyst.

**20. The Vagus Reflex.**—This consists in a peculiar humming sensation in the head due to pressure on the vagus. It has been given this name by Mays, though it has been noted by Waller as early as 1870. He reports a number of cases where it existed and was accompanied in some cases with sweating and tingling in the arms and helplessness in the lower extremities, which are hardly accounted for by the known effects on the nerves. In none of the cases except the first and second was there any marked lesion of the pulmonary organs, though from the relations that exist between vagus pain and pulmonary disease it is quite clear that the former is very frequently a premonitory symptom of the latter and therefore an important diagnostic sign and therapeutic indication.

**21. Knee Joint Auscultation.**—The method of studying the knee joint by auscultation is described by Blodgett, who uses the full-sized Bowles' stethoscope, with a soft rubber cup sprung over the diaphragm. He has examined 100 cases and gives illustrations of his method of examination showing the sounds elicited by dots and dashes. Most of these were normal joints and gave the normal variations of the sound. He also gives an example of the various pathologic conditions showing their variations in the sound produced. He thinks that with a trained ear and careful examination of the cases with special reference to the structural state of the knee, etc., this method may have a certain amount of value and deserves further investigation.

**23. Roentgen Rays.**—Reck describes the different kinds of injuries from the Roentgen rays, illustrating them, and reports experiments on the lower animals as to their effects in producing burns, etc. It is difficult to explain their origin, but he thinks it can best be done on the basis of clinical observation. He calls attention to the fact that burns should be treated as such and the main difference between the ordinary burn and tissue changes caused by the Roentgen rays exists in the later development of the latter. A peculiar chemical influence of Roentgen light is so exercised that the nutrition of the cells is impaired and it is only when the impairment has reached a certain degree that the burns occur and they are influenced mainly by the power and amount of the rays and the susceptibility of the patient. He thinks that from a pathologic consideration rules may be deduced for the therapeutic utilization of the rays. The most obvious therapeutic treatment is that for hypertrichosis, but he gives quite a list of disorders which he thinks may be amenable to this agent, suggesting individualizing, using tubes of low vacuum and care in each case as to individual susceptibility. He thinks there is a positive future for the method. The patient, however, should be informed of the risks of burns in any case. The treatment of the Roentgen-ray burn is the same as that of any other. For the simple dermatosis (or burns of the first degree) application of Burow's solution are most comfortable to the patient. For the bullous form (second degree) a xeroform gauze-dressing, after the blisters are opened and removed, is indicated for the first few days. Later he recommends a dressing of a 10 per cent. xeroform lanolin ointment, which is changed daily, provided there is but scant secretion. The necrotic form (third degree) requires speedy removal of the mortified tissues, the after-treatment being conducted as wound treatment.

**24. Cystotomy, Suprapubic.**—Seven cases are reported by Lilienthal, 5 cured, 1 death, and 1 failure. He believes in suprapubic cystotomy, though he admits that it can not be applied to all cases alike, but he thinks as a general rule it should be the first step in the operative care of any form of persistent obstruction. The steps of the operation as followed by him are: 1. Washing out the bladder, leaving the catheter in; incision of the tissues through the linea alba; retraction of the recti; inflation of the bladder with air, using an ordinary atomizer bulb fixed to the catheter. Palpation of the parts through the wound; pushing up the peritoneal reflection; opening the bladder between two retracting sutures. Exploration of the viscus with the finger, then by the eye, raising the pelvis if necessary. Snipping the mucous membrane covering the

most prominent portion of the prostate and enucleation of the gland with two fingers of the left hand while an assistant with a finger in the rectum supports the parts. A peritoneal opening may or may not be made, according to the necessities. He believes that with a competent nurse the bladder and the laceration in its floor can be perfectly drained with a continuous siphon apparatus without the opening from below. If perineal drainage is decided upon, however, it is easy to cut down upon the beak of a sound placed within the space left by the removal of the prostate. He prepares his patient with free purgation and diuresis, the latter being specially important.

**25. Alcoholic Amaurosis.**—A case of amaurosis due to ethyl alcohol is reported by Van Fleet, who notices the danger of wood alcohol especially. He thinks that it should be pointed out to the people that methyl alcohol is a positively dangerous substance producing even permanent blindness with sufficient exposure, and also the possibility of other forms of alcohol doing this if sufficiently concentrated.

**29. Obstetric Forceps.**—Two rules laid down by Smith are, never to use forceps until the woman has been twenty-four hours in labor if the first confinement, and twelve hours in the second or subsequent ones, unless there is some urgent indication to do so. Never use forceps to save one's own time. He thinks that in many cases injury to the mother is produced by too early employment, and he calls particular attention to the danger of using forceps when there are no uterine contractions and the possibility of injury to the child.

**33. Ectopic Pregnancy.**—From a general review of the subject Browd recapitulates as follows: 1. Early ectopic pregnancy runs a treacherous and uncertain course. 2. Symptoms of pain, tumor or oozing of blood are not the absolute signs of an early ectopic gestation, but their existence must be considered *cum grano salis*, and each case must be observed *per se*. 3. Clear history can not always be obtained from the patient, and the period of lactation will still more darken the clinical history. 4. Microscopic examination of the uterine scrapings, presence of decidual cells or chorionic villi find advocates in many observers, find also as many opponents. As regards treatment the use of the electric current has been advised, but the tendency is towards abdominal section in every suspicious case. Curetting does more harm than good in many cases of suspicious oozing. Probe puncture may be the cause of future infection. So-called suspicious cases with the suspicious tumor in the Fallopian tubes, he thinks, should not be kept under long observation until it is "too late to mend" but be operated upon at once. He draws an analogy between cases of early extra-uterine pregnancies and cases of suspected appendicitis. In both early operation is advisable. Exploratory laparotomy under present conditions gives perfect results and will be justified.

**37. Bile Pigments and Bile Acids.**—Croftan concludes his paper in this number, giving the results of experiments showing that trypsin is in part normally absorbed from the intestine, but that the greater portion reaches the liver via the pancreatic veins in the portal blood or via the lymphatics in the hepatic artery. In other words, that the internal secretion of the pancreas plays a greater rôle in the process of intracellular digestion than the external secretion. He concludes that if trypsin acts in the presence of dextrose on hemoglobin the formation of bile products may be carried on in any part of the body wherever hemoglobin is present with these substances. The burden of proof is imposed on us not to show why bile pigment and bile acids are formed in the liver, but to show why they should not be formed elsewhere. He reviews the arguments in favor of the formation of bile acids and bile pigments in the liver alone, showing what he considers to be their fallacies.

**38. The Public Unrest.**—The public tendency to have recourse to quackery, etc., is noticed by Silver, who maintains that we should seek to bring under one banner all the legally qualified members of the medical profession to combat the evil. He thinks that two lines of action are open: 1. To let things drift. He thinks the world is growing better in medi-

cine as well as in other respects and that in time these deplorable conditions will cease to exist. 2. That the State Society at its meeting propose a conference by committees with the sectarian societies, looking towards a solution of the difficulties which exist in the way of more perfect union of all the medical forces. If we should assure them that we only ask that they practice medicine in their own way and not trade upon a name, not relinquishing a conviction or demanding change of practice, he thinks, union could be quickly consummated. The main difficulty in the way is the vested interests of the medical colleges and the medical journals.

39. **Gelanthum.**—This is a thick, gelatinous, transparent, amber-colored fluid, recommended by Unna of Hamburg as a water-soluble vehicle for dermatological applications. It holds in solution 50 per cent. ichthyol, 40 per cent. salicylic acid, pyrogallie acid and resorcin, 5 per cent. carbolic acid and 1 per cent. bichlorid of mercury, thus making it of special value for the local application of those remedies which precipitate and coagulate such menstrua as traumaticin zinc-gelatin, collodion, etc. He speaks particularly of the use of gelanthum with 50 per cent. resorcin in the treatment of lupus erythematosus and reports two cases where it seemed to materially aid recovery. While two cases are not sufficient to form a correct opinion, anything that may appear to be of material benefit in this disease should be looked upon as a matter of importance.

43. **Treatment of Tuberculosis.**—Quimby divides the treatment of tuberculosis into systematic defense, calling special attention to the importance of nutrition. Diet stands first; it is only when the nutritive processes can be forced that feeding is curative. Stimulation of digestion is important. While the patient is eating, stimulation of digestion and the assimilative function is of utmost importance. He uses functional stimulants such as aromatic bitters, most frequently Warburg's tincture, also hepatic stimulants with which he combines some kind of oil. When there is necessity for strong hepatic stimulation, as shown by constipation, castor oil is chosen. When these symptoms are relieved olive oil is substituted. To attain satisfactory results he gives oil with mercury and arsenic which have a powerful and valuable influence on the processes of retrograde and constructive metabolism. The next thing is to treat the circulation. He passes by hydrotherapy as being fully appreciated, but mentions specially dry friction on the back as being remarkably efficacious in relieving pulmonary congestion and quieting respiration. He also notices the pneumatic cabinet as a valuable means of influencing both systemic and thoracic circulation, and while some have spoken of the danger of hemorrhage being thus excited we have no measure at our command for the moment to be compared with it for the arrest of existing and the prevention of recurring hemorrhages. Turning to the antagonistic forces, he refers to the mechanical ones, and says the utmost disregard for mechanical conditions in the lung, as potent destructive conditions in phthisis, is one of the most remarkable aberrant manifestations of modern medical thought. It is perfectly possible to remove retained secretions, open up collapsed and obstructed tubes and alveoli, absorb inflammatory exudates, and loosen or absorb pleuritic thickenings and adhesions by mechanical means. No treatment of pulmonary tuberculosis is rational or complete which ignores these mechanical conditions. Two possible lines of attack are available against the toxic forces, that is through the bronchi, and by the circulation. He doubts how far antiseptic drugs excreted in part by the lung affect local toxic conditions, but the testimony in their favor seems to prove they have a certain value. Direct action upon the pulmonary toxins implies the use of antiseptic inhalations, and while they do not arrest them they do diminish pulmonary infection. The great danger in their use is attempting too much. The agent chosen should be as little irritant as possible. For this he uses nothing but alcohol, formalin and ozone with various balsams for flavoring. Whatever the antiseptic, it should be given by cold vaporization and he finds this result most satisfactorily accomplished by wetting cloths with formalin and hanging

them in the chamber. Anyone persisting in the use of such a measures, he believes, will find that the case does better with than without it. The secondary or toxic conditions in toxemias are not to be overlooked and justify regular flushing of the colon with small antiseptic solutions in every case of tuberculosis. Frequently fever and febrile exacerbations, etc., will be found to depend solely on infection from the colon.

44. **Surgery and Tuberculosis.**—Le Boutillier reviews the surgical treatment, finding but little in favor of the injections into tubercular pulmonary foci; they have been practically abandoned. The testimony appears to be that good results have followed the Murphy method of introducing nitrogen gas. Fit cases for extirpation are only those in which there is a single small lesion, and as good hygienic treatment is often sufficient for these, operative measures do not arouse much enthusiasm. However, surgery may come in play in complications such as pulmonary hemorrhage, pneumothorax, and incision into the cavities may be of advantage in some cases, such as where there is a single moderate-sized cavity and little other pulmonary involvement, and the general health is good. Here it is simply a case of draining a septic focus and while there is opposition to the course there is still some reason for its practice. In these cases of cavities the nitrogen method should be given a trial unless pleuritic adhesions are such as to prevent its efficient action. Tuberculous empyema, of course, calls for early surgical intervention.

45.—See abstract in THE JOURNAL, xxxvii, p. 1337.

48.—See abstract in THE JOURNAL, xxxvii, p. 137.

55. **Chronic Gastric Catarrh.**—The two lesions which require therapeutic treatment are, according to Ewald: 1, diminution in the secretion of HCl and pepsin; 2, weakening of the motor function of the gastric musculature. The disturbance of the secretory function of the gastric mucosa can be met in no better way than by the administration of HCl, given in sufficient doses so that the deficiency will be fully compensated for. He administers three times after each meal at intervals of ten minutes as many drops of HCl in a glass of water as the patient can bear, that is, without having too sour a taste in the mouth, but this does not bring the stomach contents up to the normal. He thinks it may be better to introduce with a stomach tube a 0.2 per cent. solution of HCl. He has given as much as 300 c.c. of such a solution twice daily after the two larger meals and has seen excellent results follow. In recent years he has not prescribed pepsin because its secretion does not suffer in the same measure as that of the acid. With this treatment he also employs remedies which directly excite the activity of the gland cells, such as bitters, particularly condurango, which he specially prefers in infusion: 20 or 30 grams infused in 300 c.c. for 12 hours and evaporated to one-half that quantity by gentle heat. He advises this at the same time with some other remedy which increases the gastric motility and none here is as efficient as strychnia in the form of tincture of nux vomica. He puts 5 grams of tincture with 5 grams of HCl into the above infusion. Massage when skillfully performed, but only then, is valuable; he uses electricity by the intragastric method. Turck's pneumatic gymnastics of the stomach has not been tried by him, but he has the gyromele and though it appears dangerous he has never seen any bad effects from it. It should be used, however, with caution, for fear there may be some latent ulcer. The needle spray described by Einhorn has also been used by him. For removing fermenting masses he advises gastric lavage and internal antiseptics to limit the production of new fermentation. For this he employs resublimated resorcin, giving it in combination with bismuth salicylate, that is, 5 grams of resorcin, 10 of bismuth salicylate, with 15 each of bicarbonate of soda and sugar. The dose is a small teaspoonful every two hours. This does not interfere with the other remedies mentioned. Regulation of the bowels and diet is also mentioned. Meals should be moderate; the patients should not eat to a full satiety. Drinks should be always lukewarm; strong alcoholic and carbonated drinks should be excluded. Proper care of the teeth and mastication should be attended to and food selected that will be pen-

etrated by the gastric juices, excluding therefrom hard-boiled eggs, fat meats, and fat cheeses. The so-called red meat is sometimes bad on account of the high percentage of salts. The manufactured foods and those prepared from milk can be used to advantage. Fresh bakery products should be avoided and carbohydrates used with care. Milk is theoretically the best food, but it does not agree with everyone, but he speaks well of the use of evaporated and pulverized milk of which 100 grams correspond to about 1 liter of milk as being of value.

57. **Ischio Rectal Abscess.**—Martin first discusses the anatomic data and the causes of the infection and calls attention to the fact that every abscess of the ischio rectal form, if left untreated and in some cases with the best of treatment, will result in some variety of fistula. Conversely, every fistula is the result of an abscess, hence the importance of early diagnosis and treatment. He calls attention to the fact that many physicians who are punctilious in other points neglect examination of these parts. The symptoms alone should suggest that the case is of an inflammatory nature and not one of hemorrhoids. A throbbing pain felt at one side of the anus, difficulty in sitting, sleeplessness, impairment of sexual function, etc., with reddening of the skin and swelling, and if the disease is seen late fluctuations, are characteristic. He condemns positively the use of hot poultices, and in most cases much trouble will be avoided by thorough division of the sphincter muscle. He administers hypenitrous oxid in these divisions, as the patient reacts quickly and does not have to be confined to bed afterwards. In operating on these abscesses local anesthesia is always used and he operates by making a long incision through the long axis of the abscess extending into the healthy tissue at each end and connects this with one from its middle in T-shape and takes out a large piece of triangular tissue, enucleating out the necrotic tissue, having the cavity swabbed with carbolic acid or tincture of iodine, and packed with pledgets of absorbent cotton saturated with acetanilid ointment, 1 gram to the ounce. After applying a generous pad of cotton held in place by a T-bandage the patient is left to his resources until subsequent dressing. The wound is left to heal by granulation; the mistake is in allowing the skin to heal before granulation is complete in the deep parts of the cavity. Every portion of the wound should be probed at each dressing to break up adhesions and discover any new sinuses. He sums up by giving the following six short rules: "1. Examine your patients carefully. 2. Do not use poultices. 3. Operate immediately. 4. Give plenty of room for drainage. 5. Employ a local anesthetic wherever possible. 6. Do not neglect your patient after operation."

60. See abstract in THE JOURNAL, xxxvii, p. 853.

61. See abstract in THE JOURNAL, xxxvii, p. 1410.

65. **Tetanus Following Aseptic Celiotomy.**—Coe reports a case of tetanus occurring in a patient after apparently aseptic celiotomy. He goes over the literature to some extent and summarizes that it is a rare and peculiarly fatal complication of abdominal section and since the site and mode of inoculation are practically unknown, intelligent prophylaxis is impossible. When a sporadic case occurs in a hospital, not only should extra precautions be used to secure rigid asepsis, but the air of the operating room should be examined and purified by fumigation, with cleansing of the floors, walls and ceilings. Preventive inoculation should be employed for several days after the outbreak. It is hopeless to try to locate the site of infection and to destroy the bacillus at this point in abdominal section. The efforts of the surgeon should be directed to diluting and neutralizing the poison by injecting into the blood large quantities of normal salt solution containing the serum. While subdural injections are safer and are probably as efficacious as intracerebral, these cases are so desperate that we should not shrink from any measures which promise immediate relief.

66. **The Angiotribe.**—The instrument and his method of operation are described by Ellis, who finds that it has many important functions. It is inapplicable to control hemorrhage in sections or wounds of the substance of such friable organs as

the liver, spleen, or kidney, but its utility in retro- and trans-peritoneal nephrectomy and in splenectomy is evident. Its hemostatic action is serviceable in gastrectomy and in fact it can be utilized to advantage in any operation of any magnitude in the abdominal and pelvic cavities and is especially useful in vaginal hysterectomies and also supra-vaginal hysterectomies. For the removal of adnexa or excision of the small ovarian ligamentous cyst it can be absolutely depended upon for hemostasis. He thinks it is not useful in complications of the appendix when the stumps can be satisfactorily dealt with after other methods, but it is frequently serviceable in the management of redundant meso-appendix. Its value is not confined to abdominal operations. He has found no better method than this for the operation of thyroidectomy and it has done him good service in many other operations, such as castration, operation for elephantiasis and for hemorrhoids. Its use, of course, in the treatment of vascular pedicles is noted and recommended with certain limitations, but small supplementary ligatures are of value, against the possibility of secondary hemorrhage.

67.—See abstract in THE JOURNAL, xxxvii, p. 1695.

68.—Ibid., p. 1410.

69. **Curettage.**—Hyde summarizes the limitations for dilatation and curettage as follows: As a possible factor to overcome sterility: The operation is only warranted when based on tenable premises, the competency of the husband, the absence of any serious adnexal lesions, incomplete development of the genital organs, vaginismus, or malformations. Excluding or correcting these, the operator should certainly dilate or curette. It also offers relief in many cases of menorrhagia or metrorrhagia and is of great benefit for increasing the patency of the canal in some small anteflexed uteri. For securing scrapings for diagnostic purposes it is of decided value. In removing retained secundines the question is whether to employ a sharp or dull curette. He prefers a large, sharp one, and has seen as profuse a hemorrhage follow the use of the blunt curette as the other. As a preliminary to certain operations on the uterus before a trachelorrhaphy, before hysterectomizing cancerous uteri, or section to relieve posterior adherent uterine displacements, etc., it has its value, but he condemns especially the rough curette before trachelorrhaphy. He does not believe in packing the uterus after a simple curettage. The only time he packs is in the presence of persistent or alarming hemorrhage after removal of retained secundines; ordinarily there is no need for it. For removing septic foci, its utility has been much debated. If general sepsis is present he doubts the advisability of the curette. If there is septic material, pus foci, or retained placenta, it would seem that they ought to be removed by gentle curettage, not attempting to reach "hard pan." A few of the contra-indications are inexperience, and the presence of inflammatory conditions. He wants to say that it is not a simple operation, but one that may be attended with the gravest dangers; that not enough attention is directed to pelvic conditions before curettage; that the indications for it are positive and the contra-indications should always be considered. Finally, that the operation demands experience, thorough asepsis and knowledge that severe accidents may occur at any moment even to the best operator.

72.—See abstract in THE JOURNAL, xxxvii, p. 1410.

78. **Rare Papular Disease.**—Fox reports a case where there was hard papular eruption with severe itching in the axillary region and to a less extent over the pubic region. The suffering of the patient was extreme and insomnia marked. Very little relief was obtained by treatment. The histologic changes consisted of hyperkeratosis involving chiefly the sweat-duct orifices, their intra-epidermic portions and the orifices of the hair follicles, with consecutive hypertrophy of the stratum spinosum (acanthosis) surrounding the altered sweat ducts and hair follicles. With this there was mechanical dilatation of the coiled glands which result in changes in their epithelial lining and inflammatory changes of a more or less chronic character in the derma. The histological picture was similar to that seen in porokeratosis as is shown by the illustrations.

**82. Club Foot.**—McKenzie reviews the anatomical conditions and claims that the proper time for operating is about the time the child begins to walk. Then the steps to be taken will depend much upon the resistance offered. In some cases the correction may be fully rectified by the band and fixed dressing. Assuming always that the deformity of the foot *per se* has been over-corrected, attention should be given to the equinus, and here section of the tendo achillis is almost invariably required. He describes his method of cutting through the tendon subcutaneously and the plantar fascia, the internal lateral ligament and sometimes the long plantar ligaments. When the skin offers definite obstruction to further replacement he refrains from further correction and applies fixation dressing and after several weeks it is ready to yield, and another correction may be made. Dr. Phelps's open section is not, he thinks, advisable. In any case the most frequent operation required than correction that can not be made readily with the hand is severance of the plantar fascia. This should be done close to the os calcis attachment and the long plantar ligament may be reached and cut in the same operation where one enters behind the arteries and hemorrhage is not troublesome. If the obstruction appears to be much more toward the inner border of the foot the tendon of the tibialis posticus may be cut simultaneously, which must be done just below and anterior to the internal malleolus. The next obstruction most likely to need the attention is from the internal lateral ligaments of the calcaneo-scapoid. The tenotome may be so introduced as to pass parallel to the artery, and extensive section be made without causing much hemorrhage. This is all the knife is required for in the vast majority of cases. Manipulations with the hand or wrench usually suffice; the latter may be required in adults. Great importance is attributed to the dressing. Absorbent cotton should be applied so that the plaster dressing can be put on without causing abrasion, and the foot held in the position as nearly approaching correct position as possible. The pressure should be even to avoid sloughs and the dressing allowed on from two to six weeks, when it should be removed, and after a couple of days a second one applied, the two days being utilized in removing the old epithelium by bathing. Nearly always in this way, he says, the deformity can be corrected in two to four dressings, and after the removal of the last one boots should be worn in daytime, and night braces every night. \*

**85. Scarlet Fever.**—The rigid adherence to the following suggestions will, according to Ames, eradicate scarlet fever: "1. Every suspected case should be promptly isolated until the diagnosis can be positively confirmed. 2. After confirmation, make isolation absolute, and report the case to the health department. 3. Instruct the family to keep the patient isolated until all signs of peeling are invisible. 4. All members of the family who desire to leave the house must do so the first day after their clothing has been disinfected. This will take six hours, as all their apparel must be placed in a sealed room and exposed to formaldehyd gas for at least that length of time to insure public safety, and they must remain away until quarantine is removed. 5. No person should leave the infected area after fourteen days' continuous exposure, unless the sick patient is free from desquamation. 6. The attending physician should have as little contact as possible with the patient; cleanse his hands thoroughly, and disinfect his clothing before entering another house. 7. The character and duration of the isolation must be left to the public health department. Thorough disinfection with formaldehyd, 10 ounces to 1000 cubic feet, the germs having now been corralled, will destroy them and thus end the existence of the disease."

**87. Myasthenia Gravis.**—Sneve reports a case of this condition and reviews the literature. He suggests that its location must be in the cortex of the brain and thinks it possible that thorough examination and more knowledge of the normal, chromoplasmic structure and the function of the neuroglia will reveal the changes, which will not only clear up the pathology of this affection, but will also help us to understand better the phenomena of sleep, hysteria, hypnotism and allied states.

Critical blood examination by an authority threw no light on the subject in his case, though the abundance of large lymphocytes was of interest. He holds that electricity is indicated as well as exercise and cold bathing under the watchful eye of the physician, though the exhaustion of the muscular system by electricity might be very dangerous; hence arises the necessity of mild applications and great caution in the use of these methods. In conclusion he calls attention to the quite similar physiologic action of curare to the disease in question.

**88. Anesthetics.**—From an extensive experience in nine years' practice as an anesthetist, Magaw has come to believe more in the ether-drop method in the majority of cases as the safest, though perhaps a little more troublesome to the operator. The use of chloroform which has been tried in all sorts of cases is considered rather more dangerous. Nitrous oxid gas as a preliminary to ether has been tried, but the benefit seemed to be slight. The main thing to recommend it is that the patient seems to lose consciousness more quickly. For short minor operations nitrous oxid gas is far superior to either chloroform or ether. All patient are anesthetized in the operating rooms, merely giving the operator time to prepare. The inhaler used is the Esmarch, with two thicknesses of stockinette, changed after each patient. In giving ether she commences with the drop method slowly and carefully with as much air as though it were chloroform, until the patient's face is flushed, when she uses a large piece of surgeon's gauze of several thicknesses and keeps adding a few more pieces of gauze until the patient is asleep. The gauze is then removed and the anesthetic continued with the same covering as at the first. If any degree of rigidity persists the patient is not etherized. She considers touching the conjunctiva a dangerous practice, as it might infect the eye. In the condition of complete anesthesia respiration should be regular, inspiration deeper and often accompanied by snoring, expression peaceful, eyes closed, and all the muscles relaxed. For quick breathing or profuse secretion of mucus, lift the mask and allow several breaths of fresh air. Then continue with the ether. In gall-bladder work especially, the patients are sometimes noisy, as coming in contact with the diaphragm causes an increased and irregular respiratory rhythm which is mistaken for an indication for more anesthesia. If the patients have already reached surgical anesthesia this irregular respiration and grunting does not interfere. There is no need of increasing the dose. The same symptoms may follow operation on the sphincter muscles. Patients who have had peritonitis require almost a dangerous amount of anesthesia to produce relaxation of the abdominal rigidity. In cases of the tongue falling back raise the lower jaw up and forward, not using the tongue forceps, but catch the tongue with a piece of gauze and draw it out and up toward the nose and a little to one side, and withhold the anesthetic. In alcoholic cases and operations on the stomach 1/8 of a grain of morphin before operation may carry the patients through better and with less ether. Chloroform should be given with more air and less quantity and with the regular drop instead of the stream. It should be slowly and carefully given, the pulse being taken at the facial and temporal arteries. The anesthetist should never allow himself to be hurried. The mask should always be held so that the patient can get a liberal supply of air while administering chloroform to avoid choking and struggling, and any irregular and shallow respiration should lead to the prompt withdrawal of the mask. A rapidly dilated and fixed pupil always indicates danger, while a pupil contracted to normal size or a little less indicates surgical anesthesia. Blanching of the lips, ears and nose show the need of more air. All these symptoms should be watched and no one of them relied upon. Statistics are of very little consequence as to the amount of ether and chloroform required. Just as much is needed as will do good work and not a drop more. In giving nitrous oxid a dental apparatus is used. The change to ether is made quickly, ether is crowded, air excluded, the gas abandoned altogether. The Esmarch mask is used for this purpose with several thicknesses of gauze for a closed cone, and after the patient is fully under the drop method on the orig-

final cone. To prevent after vomiting various things are recommended, but since only about 40 per cent. have this symptom it is hardly worth while to submit all to such remedies as vinegar and saline solution.

102. **The Cortical Function.** Wright's article is an argument for antimaterialistic views in regard to the functions of the brain, and contains text books for using such expressions as idea cells, centers for emotion, attention, etc. The point he specially emphasizes is that the function of the brain is to transmit impulses and impressions only and that intellectual processes are carried on independent of the brain cells entirely. This view, he holds, aids us in the solutions of many of the problems that confront us. Psychology as well as physiology must be drawn upon to understand the functions of the brain cortex.

118. **Yellow Fever.** Oliver's article is a plea against the theory of the exclusive transmission of yellow fever by the mosquito and in favor of the fomites theory and the necessity of quarantine.

4. **Volkmann's Contracture.**—This phenomenon consists in contraction of the fingers and sometimes of the wrist, coming on rapidly with loss of power, though not absolutely, in the forearm muscle after a severe injury, usually in the region of the elbow joint, and generally in young children. The deformity is due to changes in the flexor muscle without injury to the peripheral nerves, caused in many cases by tight bandaging and pressure of splints. In some cases, however, splint pressure may have no effect, and Dudgeon thinks it is far more probable that it is the result of a combination of large effusion in the soft parts with splint pressure in most cases. The great feature in the history of a case of this deformity is the onset of paralysis of the limb, with contracture. The fingers sometimes become blackish and frequently swell. There is rarely any pain until after the removal of the splint when the forearm sometimes is tender. There is often sloughing of the skin, usually in the middle or upper part of the flexor surface of the forearm. The fingers are at first simply flexed, but soon pass into the characteristic position. "With the wrist extended the metacarpo-phalangeal joints are extended also; the interphalangeal joints of the fingers and the terminal joint of the thumb are, however, strongly flexed, so that the tips of the fingers touch the lower part of the palm, and no reasonable amount of force seems capable of straightening them; but as soon as the wrist-joint is flexed to a right angle then the interphalangeal joints can be easily extended. In very bad cases the wrist becomes strongly flexed, and is incapable of extension. The hand is pronated, and the forearm is generally semi-flexed. The flexor muscles of the forearm seem hard, firm, and much wasted. A thickening is sometimes felt in the soft tissues, usually in relation to the pressure sore which is so frequently present. A swelling, bony in character, is sometimes to be found at the lower end of the humerus, generally at the inner side. Sensation may be normal, or there may be partial or complete anesthesia; this is dependent on the condition of the peripheral nerves. There are thus to be seen usually three grades of this deformity: 1, partial contraction of the fingers; 2, the hand in the typical position; and 3, strong flexion of the wrist and fingers, without any power of extension. There are no true trophic lesions in pure ischemic myositis, but the hands are frequently cold and blue and the skin smooth. The fingers frequently swell when the arm hangs down by the side for some time. It is said that the joints become ankylosed, similar

to the ankylosis in traumatic arthritis, but I could find no such case in the literature or any mention of such a condition having been recorded; in those cases in which any reference was made to the joints they were always said to be normal. In well-marked cases there is as much shortening of the bones as is met with in acute anterior poliomyelitis, etc." Normal electrical reactions are characteristic. The pathology of the condition according to the different authors is reviewed. It is shown that it may occur after severe cold, and possibly there may be an escape of synovial fluid with blood, producing deformity in some cases. The condition of the muscles when examined by the surgeons in operations shows them wasted, pale, firm and dry, and that they have undergone a sort of fibrosis. The differential diagnosis as distinguished from ulnar, median or muscular spiral paralysis, poliomyelitic contraction, Little's disease and the so-called functional disease, is noticed. Dudgeon does not believe in the bad prognosis claimed by Volkmann for this condition. Some of his cases have recovered, and he agrees rather with Anderson, whose opinion is directly contrary to that of Volkmann, that the affection may be generally retarded by the systematic active and passive movement with massage, with, if necessary, the galvanic current. He advises the delay of any surgical operation for such condition for some time, at least three or four months.

5. **Revaccination.**—Andrewes analyzes the statistics of the revaccination of the female staff of St. Bartholomew's Hospital. He finds that a very large percentage of those previously vaccinated had good vaccination results. Among the ward maids and domestic servants, who for the most part had not been vaccinated since infancy, there was true vaccinia in 76.36 per cent.; imperfect vaccinia, 20 per cent.; and negative results in 3.64 per cent. Among the 88 nurses who had been vaccinated on beginning of their employment, there were 27.27 per cent. of perfect vaccinia; 54.54 per cent. of imperfect vaccinia and 18.18 per cent. of negative results. Among the senior nurses and ward sisters who had been long in the service and not recently vaccinated there were 40 per cent. perfect vaccinia; 40 per cent. imperfect and 20 per cent. of failures. Of 61 cases who had not been successfully vaccinated since infancy there were 81.96 per cent. of perfect vaccinia; 13.11 per cent. of fair vaccinia; 1.66 per cent. feeble vesicles, and negative results in only 3.32 per cent. The results indicate the necessity of revaccination, and that during the third decade of life some 80 per cent. of those vaccinated in infancy are most imperfectly protected against smallpox. As regards those who have been revaccinated, individual susceptibility plays an important part, and some are so susceptible as to require revaccination after six or seven years. He thinks investigation along this particular line is desirable, for there seems to be a dearth of accurate information in regard to the matter.

16. **Enuresis.**—The suggestion of Parnell is to employ a strong solution of silver nitrate to the neck of the bladder and urethra, a plan he has found mentioned only in Holmes' "Surgery." He reports two cases. In order to bring the solution more thoroughly in contact with the urethral canal he has devised a small dilator with straight blades, which is very effective. No oil or ointment should be used, but the blades should be moistened with distilled or sterilized water and, after the urine has ceased, a little ointment smeared over the outer parts, and a probe well armed with cotton wool saturated with the solution passed between the blades and withdrawn two or three times. The instrument is then removed and again inserted at right angles with the former position, the urethra again dilated and the swab applied so as to ensure that the whole of the canal comes in contact with the solution. He attributes considerable importance to the moral effect of the treatment. He has not complicated its results by the administration of drugs, but thinks it might be still better with proper medication. He suggests the effect of the mechanical action caused by the slightly swollen urethra after treatment, but the real value is the breaking down of the bad habit for a week or more.

**18. Phagocytic Action.**—The method recommended by Leishman aims at enumerating the number of bacilli or cocci phagocytized within a definite time by the polymuclear cells of the blood under examination, obtaining the average of these variations and comparing the results with that of the control blood, preferably that of the observer, put up under identical conditions. He makes agar emulsions of the germs he desires to investigate, insuring the normal distribution through the emulsion. He adds a measured volume of blood to equal the volume of the emulsion on a slide or watch glass. This is transferred to the prepared slide and covered by a cover glass and precisely the same procedure is gone over with the control blood. The slides are then placed in moist chambers and left in an incubator at 37° C. for one-half hour. The blood under the cover glass remains liquid for hours and the phagocytes have a chance to exercise their power on the surrounding germs. At the end of half an hour the slide is removed and prepared for staining, loosening the dried edges with a little normal salt solution, and removing the cover glass, when the films are dried in the incubator for a minute and stained for the microscopic examination. He uses a staining method devised by himself and published in the *British Medical Journal* of September 21, 1901, and finds little difficulty in enumerating the number of germs contained in each phagocyte. The method is, he says, obviously far from the ideal one. The dilution of the blood with salt solution, variations in the number and possibly the virulence of the germs introduced, and, perhaps, the variation in the phagocytic power of the observer's blood from day to day are some of the objections, but the results so far obtained have proven surprisingly regular and the identical conditions of the blood under examination and the control blood at least partially annul the effects of variations due to differences in the number and virulence of the germs. He reports some of his observations, which indicate that the method has some particular value.

**25. Irrigation of the Intestines with Hydrogen Dioxid.**—Roger has witnessed remarkably prompt cures of dysentery-form colitis treated by one to three injections a day of a pint or a quart of diluted hydrogen dioxid, after the failure of other measures. The violent pains disappeared after two injections; the diarrhea was arrested and the fever declined. He considers this lavage of the intestines an extremely valuable measure in all cases of excessive putrefaction in the large intestine. On account of its hemostatic properties it might be found useful in hemorrhagic affections of this portion of the intestines. Rocaix has recently advocated it and described its successful application in cases of acute dysentery in children. Roger states that the result of this treatment is also encouraging in mucous membranous colitis, although less striking than in the other variety. He prepares the fluid fresh for injection by adding 100 c.c. of a 12 volume hydrogen dioxid to 900 c.c. of water containing in solution 5 gm. of sodium chlorid, 3 gm. of sodium phosphate and .5 gm. of sodium bicarbonate. It is injected into the colon through a flexible sound under weak pressure.

**26. Medical Treatment of Menstrual Troubles of Utero-Ovarian Origin.**—Vidal remarks that many utero-ovarian affections are due solely to disturbances in the innervation or circulation of the parts, and medicinal and surgical treatment is powerless in these cases. They require physical measures to act on the vasomotor centers, air, sunshine, electricity, mechanotherapy, hydrotherapy and especially mineral waters. The last mentioned have a physical, chemical and dynamic power in these cases, which very few persons appreciate at their true value. They stimulate the nutrition, as can be seen by the increase of urea, phosphates and chlorids in the urine, while the uric acid diminishes. This local and general action is particularly successful in combating menstrual disturbances, whether amenorrhea or metrorrhagia predominates.

**27. Extraction of Metallic Foreign Bodies in Air Passages with the Magnet.**—De Roaldés has been making a special study of the technique of removing metallic foreign

bodies from the upper air passages, since he first suggested the use of the magnet for this purpose at a meeting of the Louisiana State Medical Society in 1899. Garel of Lyons recently removed a small nail in this way from the right bronchus, at the sixth interspace, through a tracheotomy wound. The distance between the magnet and the nail was at least 5 or 6 cm. De Roaldés has had no opportunity to practice his technique, but he has established by numerous experiments on the cadaver, that a metallic foreign body in the nose or nasopharynx promptly emerges when a Haab magnet is brought close to the nostrils. A preliminary application of suprarenal extract or of cocaine would facilitate the extraction on the living subject. Objects placed in the deeper passages were easily drawn out by means of the magnet through a tracheotomy wound. The most interesting part of his experiments was his successful removal of such objects with a very strong magnet applied to the outside of the chest and slowly moved upward toward the tracheal wound. It was impossible to bring them into the mouth by this means. The conditions were not favorable, owing to the shape of the Haab magnet for this part of the procedure, but he is convinced that improvement of the technique will render it possible to extract a metallic body in a bronchus or in the trachea, through the mouth, with the aid of general narcosis, appropriate position of the patient and fluoroscopy or bronchoscopy. The object can be mobilized perhaps by turning the current on and off in rapid succession, and a flexible metal sound in contact with the large magnet may be inserted in the throat as an extension of the magnet, or the combination of a magnet inside and outside of the throat may be found useful.

**28. Latent Tuberculosis of Tonsils and Adenoid Vegetations.**—Jankelevitch concludes from a review of the literature on the subject that latent secondary tuberculosis of the tonsils is not infrequent, but that the primary latent infection is extremely rare. The cases that have been published as primary were more probably consecutive to some other latent foci. The lesion in the tonsil is usually benign and never leads to ulceration. No instances could be found in the literature of secondary infection of the lungs originating in a focus in the tonsil. Treatment can be only surgical.

**35. Diagnosis of Tubercular Peritonitis in Children.**—*Ibid.*

**36. General Contraction of the Stomach and Jejunostomy.**—Cackovic describes the symptoms of this total shrinking of the stomach as a noticeable inability to eat much food and satiety after a few mouthfuls. The small cavity of the contracted stomach is soon filled and the rigid walls do not stretch nor expel the food into the duodenum. The motor function is performed by the peristalsis of the esophagus alone. When the walls are quite rigid there is no pain, as there are no contractions, but until this stage is reached the pains may be quite severe. Vomiting occurs simply from the overflow. The stools are hard or diarrhetic, and bowels very sluggish. Left epigastric region is usually depressed. The impossibility to distend the stomach by insufflation of air or injection of water is the most significant diagnostic sign. After 50 to 150 gm. of water have been poured into the stomach tube the fluid stands in the funnel. In two cases personally observed, the patients were 36 and 60 years old. Both were evidently cases of diffuse malignant degeneration of the stomach walls, although it could not be detected by the naked eye in one, and the microscope showed only a few scattered epithelial cells in the mucous and submucous coats while the muscle exhibited evidences of chronic inflammation. In the other case there was an extensive ulcerative carcinoma, not actually circumscribed. A radical operation or even gastroenterostomy was impossible in either case and jejunostomy was done. The technical and functional results were perfect, but both patients died the seventh day after the operation, the first in progressive collapse, the other from hypostatic

pneumonia of the right lower lobe. He tabulates the details of 77 jejunostomies which he has collected, to sustain his assertion that this is by no means so severe an operation as it is usually considered. It is practicable in every case of general contraction of the stomach; the technique is comparatively simple; it does not expose the patient to more danger than any other palliative operation, and it relieves him from the torments to which he would otherwise succumb much sooner and with much more pain. Cackovic advocates jejunostomy also in case of severe stenosis of the esophagus, if gastrostomy is impossible; also for carcinoma of the stomach if a major radical or palliative operation is not indicated or not practicable; also for cases of benign stenosis of the pylorus or cicatrices of the stomach in very feeble patients; for gastric ulcer with frequent hemorrhages rebellious to treatment and threatening inanition; for intoxication from a caustic when death is imminent from inanition or rupture, or when no other operation is practicable; in case of insufficiency of the suture after an operation on the stomach, and also when a radical or palliative operation has failed or been only transiently effective. The chief point in treatment of general contraction of the stomach is to determine the amount of food that is tolerated by the patient and not surpass this. His second patient said: "I can eat two spoonfuls all right, but I throw up the third every time." Alimentary injections will be useful adjuvants and also subcutaneous injections of saline solution and possibly of olive oil. The bowels must be systematically regulated with injections and laxatives. Morphin has to be used freely.

**37. Resection of Spleen Under Hemostasis by Steam.**—Snequireff found steam a most useful aid in the resection on account of a cavernous angioma, of a portion of the spleen, 3 by 6.5 cm. in size. The patient was a previously healthy ii-para of 29. The spleen measured 14 by 11.5 cm., and a hydrosalpinx was also evident. Ligatures tore through the spleen tissue "as if it were butter," but the copious bleeding was completely controlled in twelve minutes by an apparatus which sprayed steam evenly over the entire cut surface at once, combined with the application of a slanting jet of steam to the severed arteries. He was careful to cut the surface in areas corresponding to the scope of his apparatus. When the tissue had turned a brownish green the hemostasis was perfect. The escaping steam, blood, etc., were caught on gauze compresses kept cool by pouring cold salt solution on them. The patient was dismissed cured in two months.

**39. Method of Orchidopexy.**—Hahn has treated a large number of cases of retention of the testis, since 1888, by the method described and the results have been satisfactory and permanent in every instance. The testis is released and brought down to its proper place through a canal made for it, which extends from the cutaneous incision to the lowest portion of the side of the scrotum. It is excavated with the fingers and forceps, and the testis is worked down through this new-formed canal until it protrudes through the incision in the skin of the scrotum below. This incision is sutured around the testis, leaving it projecting like a mushroom from the lower portion of the scrotum. A loose bandage is applied for six or seven days. After this interval the last few stitches are taken out and the testis is worked under the skin, which is then sutured over it, and it remains permanently in its new place. The nutrition of the testis did not seem to suffer by the procedure in any instance, except possibly in the case of one very small atrophic testis which continued to shrivel.

**44. Glycolysis.**—Bendix and Bickel state that Lépine's conception of glycolysis as due to the action of a glycolytic ferment secreted by the pancreas, is not sustained by their research. They have found that the alkaline blood is able alone to induce glycolysis, evidently by a purely chemical process, without the coöperation of any ferment. Grape sugar was destroyed in still larger proportion in a .2 or .5 per cent. pure aqueous solution of soda—that is, a fluid as alkaline as the blood. For example, 70 mg. of dextrose mixed with a .28 per cent. solution of soda and kept in the incubating oven for thirty-six hours, diminished to 64 mg. There was a loss of

20 mg. in other tests with a .18 per cent. solution of soda after 240 hours, and of 23 to 33 mg. in a 1.67 per cent. solution after 96 hours. In studying glycolysis the methods of estimating the amount of sugar must be exact, and the possibility that the grape sugar may be decomposed by the action of bacteria in some fermentative process, must be excluded.

**46. Trauma in the Genesis of Tumors.**—Schmieden describes a case of central giant-celled sarcoma of the tibia, the first symptoms of which were observed not long after a contusion of the spot. The trauma caused much pain and temporary inability to walk. In spite of this circumstantial evidence of the traumatic origin of the tumor, he discredits it, and affirms that the tumor could not have come into existence without the presence of the causal germ, no matter how pre-disposed the soil. Authors have published statistics of 13.4 per cent. tumors of traumatic origin, as in Löwenthal's report; Wolff, 14.3 per cent.; Rapok, 20 per cent.; Mass, 1 per cent., etc., but closer analysis of the cases cited shows that the attempt to trace the tumor to the trauma is very far-fetched, as for instance, Löwenthal's case of a fall from a horse, with no appreciable disturbances, and a gliosarcoma developed in the cerebellum twenty-two years later. Even in the cases of so-called chronic trauma, such as carcinoma of the lip in a smoker, the factors may be more of a chemical than of a physical nature. No evidence has yet been presented, he concludes, which establishes the fact that a trauma is able to call a tumor into being in sound tissue, and for his part, he refuses to admit the possibility.

**47. Colostomy for Chronic Dysentery.**—Nehrkorn describes a case to demonstrate the benefits that can be derived from temporary colostomy in cases of dysentery in which the hemorrhages persist in spite of all internal treatment and the patient is rapidly losing strength, or when the pains and profuse diarrheas are constant, and also when the debility is so extreme that further internal or local treatment becomes impossible. The localization of the intestinal affection determines the character of the intervention. Colostomy on the right side, cecostomy, is the operation when the entire large intestine is involved in the morbid process. It allows the diseased intestine to rest and recuperate. When the affection is limited to the middle portion of the colon, as determined by inspection and palpation during the laparotomy, the diseased portion can be resected and an artificial anus thus be avoided. Colostomy on the left side is indicated in those cases in which the sigmoid flexure is the locus morbi. The aim in this latter intervention is not so much the exclusion of part of the intestine as it is to apply local medication directly to the affected points. This was the intervention in the case described. The patient was a young cigarmaker in Baden, healthy until debilitated by several months of sporadic chronic dysentery with almost incessant small hemorrhages from the intestines. After the failure of internal medication Czerny exposed the flexure, finding it edematous and rigid from infiltration. It was fastened to the wound and two days later was opened. Circumscribed, hyperemic lumps were found in its interior, with two erosions the size of a pfennig, bleeding at the lightest touch. The colon was rinsed out once or twice a day for several weeks with a dilute solution of salicylic acid. A liter and a half could be poured in without trouble. The hemorrhages ceased from the moment of the intervention. Three days afterward castor oil was given. The patient rapidly regained strength and the artificial anus was closed three and one-half months after the operation, and now, three months later, the stools are of normal color and consistency, free from blood or mucus and the patient feels completely well.

**49. Remote Results of Exclusion of Intestine.**—Wiesinger reports the condition of two patients who were operated on more than six years ago by the exclusion of a large portion of the intestines, on account of chronic inflammation of the colon or cecum. The first patient was a woman of 31, and the excluded portion of the intestine included the transverse and descending colon and part of the sigmoid flexure. An artificial anus was made on the right side to allow local

treatment. Later the ascending colon was united to the flexure, and the artificial anus was closed. The patient has carried this long piece of excluded intestine for six years without disturbance of any kind or tenderness at any point. She feels perfectly well, has a good appetite, her bowels act regularly, she has gained in weight and attends to her business as usual. This is the first and only successful case of the kind on record. The second of Wiesinger's patients was a girl of 17 who recovered complete health after the exclusion of the terminal portion of the ileum, the cecum and ascending colon, on account of a tuberculous tumor in the cecum with a fecal fistula. Resection was impossible on account of adhesions. The patient is in good health, has held her position permanently and has recently married. The tumor has retrogressed, but the fistula still persists and has a slight transparent mucous secretion.

**51. Nerve Grafting.** Dumstrey describes a case of ulnar paralysis in a boy of 19 years, which had persisted for twenty-six months after a fracture of the elbow. As a degenerative process in the nerve was more than probable, he treated the paralysis by grafting the ulnar nerve in an oblique incision in the median nerve after first cutting the ulnar across obliquely. He fastened it in place with a single catgut stitch, and sutured the central stump of the nerve as close to the graft as possible, hoping that it might grow in time to span the gap of 4 cm. Pain was severe at first, and the lips of the wound farthest from the graft became slightly gangrenous. After freshening the lips and suturing afresh the ninth day, the wound healed smoothly. There was tingling, formication and itching in the ulnar side of the hand, and gradually, in the course of several months, the functions of the hand were regained under electricity, exercises, massage and warm baths. The patient was lost sight of before the prospects of the cure had been completely realized. Dumstrey performed a similar operation afterwards on six dogs. The wound became infected in each and the anatomic results were perfect in only two of the animals. In these the nerve fibers had actually grown in and through the graft with no accumulation of tissue. The graft looked like a normal, branching nerve, with scarcely any traces of an operation. He concludes from his experiences that restoration of function should not be anticipated until after several months have elapsed, and also that smooth, primary union of the nerves is indispensable. He does not believe that it is necessary to approximate the nerves so carefully as Gluck advocates, axis cylinder to axis cylinder, etc.

**62. Study of the Heart with the Orthodiagraph.**—Moritz gives sixteen cuts to illustrate the value of the orthodiagraph in determining the outlines of the heart. The Roentgen tube is arranged so that it can readily be moved in any direction in a level plane over the fluorescent screen. The exact points where the rays fall perpendicular to the screen are marked as the tube is moved along. It is thus possible to obtain an exact silhouette of the object, showing its size, shape and position at any time. This orthodiagraphic representation of the heart verifies and controls the results of percussion on the living subject.

**64. Silk Tendons to Correct Deformities.**—Lange improved the technique of tendon transplantation by weaving a thread of silk in the portion of the tendon split off to transplant in the paralyzed tendon, thus strengthening it and allowing more tension. He found he could suture the tendon directly to the periosteum instead of to the paralyzed tendon, thus operating entirely in sound tissue. Later, he discovered that the silk answered completely the purpose of a tendon and that it was unnecessary to slit the sound tendon. He now leaves it intact, weaves some silk threads through it and carries them down to the periosteum below where they are fastened as if forming a branch of the sound tendon. He is thus able to operate in cases in which the defect is too extensive to be bridged by the natural tendon, as well as those in which the tendon is too thin to be divided. The intervention is comparatively insignificant when the silk tendon is used. The strength of the sound tendon is not impaired, and by this

means it is possible to make an exaggerated correction without undue stretching of the natural tendon and fear of consecutive necrosis. In a case of paralysis of the peronei and extensor digitorum, for instance, in which the tibialis anticus is too weak to be divided, he weaves two strong silk threads through the tendon of the latter, parallel to the fibers, above the annular ligament. The four ends of the silk thread are passed then through the periosteum of the cuboid bone, weaving them in and out before tying them. Four months afterward the patient is able to move his foot up and down in approximately normal range, without recurrence of the previous deformity. Lange has applied these tendons in 56 cases and primary healing was secured in every instance. The threads tore through twice afterward, from imperfect technique as the angle had not been correctly calculated. There was no suppuration, but the traction from the silk threads woven in the gastrocnemius and fastened in the periosteum of the cuboid bone, was too strong for the soft parts covering them. If a cotton pad had been worn in the shoe, this mishap might have been averted. Some of the silk tendons he has thus made in various patients were 20 cm. long. The functional results have been remarkably perfect, even in case of paralysis of the quadriceps, the most difficult of all operations of the kind. For this, he transplants the biceps and the semitendinosus forward and lengthens them by a silk tendon from each, both joining together and woven into the periosteum of the tibia where they are tied. When the immobilizing cast is first removed the silk can be palpated as when first inserted, but as the limb is exercised, the silk tendon becomes larger and larger, until it feels like a lead pencil instead of a knitting needle under the skin. As it is used constantly in the movements of the parts it does not act like a foreign body, and the healing process proceeds like that of a living tissue. He is able to prove this assertion by a silk tendon removed from the knee after two and a half years of practically normal function, the patient a child who required a second operation for another cause. The silk tendon was 12 cm. long and had become encased in a sheath of normal tendon tissue whose walls were 2 or 3 mm. thick and whose lower end blended like a normal tendon with the periosteum of the tibia. A microscopic section of the new formed tendon showed normal parallel arrangement of the fibers and normal structure throughout. Among his most gratifying successes is the case of a boy of 15 with all the muscles of both legs paralyzed except the quadriceps in one and the biceps, semitendinosus and extensor digitorum in the other. He was unable to walk or even stand. One year after the operations he was able to walk without an apparatus. Another patient was a young woman of 22 with paralysis of all the muscles of the legs except the quadriceps in the left and the biceps and tensor fasciae in the right. Walking and standing were impossible, but now, a few months after the intervention, and for the first time in seventeen years, she can stand without mechanical support and is able to walk with merely the aid of two canes.

**65. Gelatin Injections as a Cure for Melaena Neonatorum.**—Holtzschmidt states that 50 per cent. terminated fatally of the 14 cases of melaena neonatorum occurring at the Woman's Clinic at Dresden during the years from 1894 to 1900, in the course of 14,203 childbirths. In 1901 every case—5 in number—was treated by subcutaneous injection of about 15 c.c. of a 2 per cent. solution of gelatin, in the chest or thigh, in two places. The hemorrhages were at once arrested in 3 of the infants; 1 required a second and 1 a third injection before the cure was complete. All recovered. No other stypic was applied, not even the precaution of cooling the milk. The gelatin was always absorbed without reaction. He concludes from his experience that in case of excessive loss of blood the injection should be repeated again the same day until the hemorrhages are definitely arrested. In order to avoid all danger of injecting germs with the gelatin he prepares the solution by adding 20 gm. of ordinary gelatin to a liter of physiologic saline solution, plugging the bottle with cotton and boiling it in the water bath for five or six hours.

The bottle is then set aside and the mixture hardens. Liquefaction of the hardened gelatin would suggest the presence of germs, and the permanently unaltered appearance of the contents of the bottle is the best guarantee of its purity.

**66. Treatment of Rupture of the Uterus.**—Wiener advocates laparotomy and suture of the ruptured uterus as soon as possible. In places where a hospital is accessible the patient should be carried there for the operation. He describes two cases, both terminating in recovery. Tampons were applied at once, internally and externally, and by this means the hemorrhage was checked and the patients were able to stand a ride of one or two hours to the hospital. In one of the cases the rupture was evidently spontaneous, due to the contraction of the uterus in severe labor. The organ contracted after the rupture and the head of the fetus acted like a tampon, so that there was no hemorrhage until after the extraction of the hydrocephalous child. Wiener believes that the cavities should be wiped and cleaned with dry compresses. The application of fluids spreads the germs over a larger surface, whereas under dry cleaning, if any inflammation follows it is restricted to a small area.

**68. Esophagoscopy, Gastrosocopy and Celioscopy.**—The instrument which Kelling uses for endoscopy of the alimentary canal is constructed on the principle of his little finger, he remarks, only instead of three joints the instrument has twenty. Like the finger, it is covered with a soft sheath of rubber. The introduction into the esophagus or stomach of this flexible tube is no more aggressive than the introduction of the stomach tube or sound. After it is in place, a stiff guide is worked into it, as the success of endoscopy of this kind depends on bringing the mouth and esophagus into a straight line, which is easily accomplished. The incandescent lamp and lenses are then introduced with a spiral motion imparted by a wheel above. The gastroscope differs from the esophagoscope only in that the lower end is bent at an angle to keep it away from the posterior wall of the stomach. The chief value of endoscopy is the early differentiation of carcinoma and the removal of foreign bodies. He relates a number of instances in which this differentiation was of inestimable benefit. In four cases in which the symptoms suggested incipient malignant disease, endoscopy revealed the integrity of the organs and indicated the nervous origin of the troubles or located them in an adjacent organ. In other cases it revealed a diverticulum, a syphilitic ulceration or mere spasm. In one case in which it established spasmodic contraction as the cause of the troubles, several physicians had previously diagnosed the case as carcinoma. For endoscopy of the abdominal cavity he first anesthetizes with Schleich's solution; then inflates the cavity through a Fiedler trocar and then inserts the smallest sized Nitze cystoscope through a second trocar. The viscera can thus be seen and palpated under the control of the eye. This method of celiotomy is aseptic, free from pain or danger and can be applied "ambulant."

**71. Connection Between Sciatica, Meralgia and Flat Foot.**—Pal describes a number of cases out of his large experience in which the patients exhibited symptoms of sciatica or meralgia or both, rebellious to all local treatment, and finally traced to an acquired talipes valgus. Appropriate treatment of the latter banished the pseudo-sciatica. No symptoms attracted attention to the foot in many of these cases. A young army officer, for example, applied for relief from intense pain in the right hip. The sciatic nerve was not sensitive to pressure but the pains involved the entire gluteal region, with slight paresthetic meralgia. Investigation showed that the patient had a flat foot which had been duly corrected for years, but he had laid aside the special footgear and had been wearing ordinary boots for the last four weeks. Return to his corrected shoes permanently banished the pains. Another case was a man of 45, subject to renal calculi. Violent pains suddenly appeared in the lumbar and gluteal region, attributed by the physician to new calculi. The patient was sent to Carlsbad where energetic local treatment of the supposed sciatica was undertaken. He returned in time, the pains still unmodi-

fied, and Pal then examined the feet and found pronounced flat-foot. Appropriate shoes corrected the condition and banished the pains. Two patients were cooks. The sciatic nerve is very little if at all sensitive in these cases. Treatment should aim to cure the contraction in the foot before the mechanical correction can be applied. Rest in bed, massage, moist compresses and gymnastic exercises are all important preliminaries to successful treatment. The position of the foot can be corrected with adhesive plaster strips in most cases, preparatory for the special shoe. The pad or special sole must be adapted to the individual case and hold the foot in perfect supination.

**74. Maggots in the Alimentary Canal.**—Schlesinger applies the term myiasis gastro-intestinalis to cases in which living maggots or flies are found in the contents of the stomach or intestines. They may occur once or repeatedly, and thus the resulting affection may be acute, subacute or chronic. Acute myiasis usually passes over without any characteristic symptoms unless, perhaps, the exceptional intensity of the pains. In some chronic cases no symptoms were noted. In one case pains and diarrhea recurred at intervals for years, but subsided each time after expulsion of a large batch of maggots. The expulsion was favored by kneading massage of the abdomen. The symptoms resembled those of a mucous colitis or membranous enteritis or merely an atypical dysentery. All the cases on record—about 100 in number—exhibited a comparatively long period of incubation before the first larvæ were expelled from the stomach or rectum, during which time various symptoms had called attention to the existence of some gastro-intestinal affection. This period of incubation ranged from a few weeks to several years in different cases. A remarkable feature of the cases was the peculiar expulsion *en masse* of the maggots. They were never found singly. Schlesinger explains this phenomenon by the colonization of the maggots in some comparatively limited space in the intestines. Some injurious influence may affect the entire colony and drive it out, while other colonies may persist undisturbed elsewhere. Another feature is the appearance of blood in the stools or vomit. This blood is probably derived from lesions of the intestinal walls caused by the direct action of the larvæ, similar to the hemorrhages in ancylostomyiasis. Migraine and neuralgic pains in side and back, or even in legs and knees, are frequent symptoms.

**78. Treatment of Fissure of the Anus.**—Gussenbaur relates the particulars of 23 male and 24 female patients whom he cured of painful fissure of the anus by merely stretching the anus until the cramp was abolished. The patient in profound narcosis, he inserts one forefinger very carefully into the anus, and then the other forefinger, then exerts gentle traction until the cramp is overcome and the sphincter becomes relaxed. The fissure may be slightly enlarged by the procedure. The anus is then wiped dry with sterile cloths and the fissure is merely dusted with iodoform or tamponed with iodoform gauze. As the patient recovers from the narcosis he experiences pain for one or two hours. After this time all pain ceases and he is permanently freed from all his previous discomfort at one stroke. The fissure heals completely in a few days to one or two weeks, unless possibly delayed by complications. Continence is restored after a few days. If general narcosis is contra-indicated, the dilatation can be accomplished without it. Local anesthesia is ineffective. This method of treatment, first introduced by Recamier, far surpasses all others in the certainty of the cure and the rapid healing of the fissure. Gussenbaur's experience has been much more extensive than the 47 cases described. He has never known any inconvenience to result.

**83. Operative Intervention for Perityphlitis.**—Zeidler believes in operating in the first stage of the process, during the catarrhal period, whether merely simple catarrhal appendicitis, or the ulcerative, parenchymatous or obliterating variety, or empyema of the appendix, chronic or latent. During the acute stage of perityphlitis he operates only when there seems to be no tendency to absorption of the inflam-

matory infiltrate and suppuration, and the suppuration is not becoming circumscribed. He would also operate at a later stage if there is a tendency to recurrence.

**85 Serodiagnosis of Tuberculosis.** Kazaninoff has been investigating the agglutinating reaction in 73 patients with tuberculosis and in 11 healthy subjects. The tests were negative in the latter in all but 2, and one of these has exhibited evidences of a tubercular affection since. The specific agglutinating reaction occurred in the tuberculous 73, the intensity dependent upon the stage of the development of the tuberculosis, its course and on the strength of the organism affected. He unconditionally confirms the assertions of Arloing and Comroux in regard to the value of this means of differentiating tuberculosis.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**AMERICAN EDITION OF NOTHAGALL'S ENCYCLOPEDIA, Variola (Including Vaccination),** by Dr. H. Immermann, of Basle, Vari-cella, by Dr. Th. von Jürgensen, of Tübingen, Cholera Asiatica and Cholera Nostrata, by Dr. C. Liebermeister, of Tübingen, Erysipelas and Erysipeld, by Dr. H. Lehnartz, of Hamburg, Whooping Cough and Hay Fever, by Dr. G. Sticker, of Gießen. Edited, with additions, by Sir J. W. Moore, B.A., M.D., F.R.C.P., Professor of the practice of Medicine, Royal College of Surgeons, Ireland. Hand some octavo volume of 682 pages, illustrated. Cloth. Price, \$5.00 net. Philadelphia and London: W. B. Saunders & Co., 1902.

**THE MEDICAL NEWS POKER FORMULARY, New 4th Edition,** containing 1700 prescriptions representing the latest and most approved methods of administering remedial agents. By E. Quin Thornton, M.D., Demonstrator of Therapeutics, Pharmacy and Materia Medica in the Jefferson Medical College, Philadelphia. New 4th edition, carefully revised to date of issue. Pp. 287. In one wallet shaped volume, strongly bound in leather, with pocket and pencil. Price, \$1.50 net. Philadelphia and New York: Lea Brothers & Co., 1902.

**ON THE CURE OF THE MORPHIA HABIT WITHOUT SUFFERING, With a Note on the Physiologic Method of Relieving the Craving for Drink.** By Oscar Jennings, M.D. (Paris), M.R.C.S. (Eng.), Fellow of the Royal Medical-Chirurgical Society. Second Edition, Revised and Enlarged. Cloth. Pp. 211. Price, \$1.50. New York: Wm. Wood & Co., 1901.

**OUTLINES OF PHYSIOLOGY.** By Edward Groves Jones, M.D., Lecturer on Physical Diagnosis in the Atlantic College of Physicians and Surgeons, and Professor of Physiology in the Dental Department of the same. With 107 illustrations. 12mo. Pp. 400. Price, \$1.50 net. Philadelphia: P. Blakiston's Son & Co., 1901.

**THE POKER GRAY, or Anatomist's Vade Mecum.** By the Late Edward Colverell, F.R.C.S., Fifth Edition, Revised and Edited by C. H. Pagge, M.B., M.S. Lond., F.R.C.S., Senior Demonstrator of Anatomy, Guy's Hospital. Twentieth Thousand. Cloth. Pp. 269. Price, \$1.25. New York: Wm. Wood & Co.

**ELEMENTARY OPHTHALMIC OPTICS.** Including Ophthalmoscopy and Refractometry. By Herbert Parsons, B.S., B.Sc., F.R.C.S., Curator, Royal London (Moorefields) Ophthalmic Hospital. Large, 12mo. Pp. 162. Price, \$2.00 net. Philadelphia: P. Blakiston's Son & Co., 1902.

**ALCOHOLISM, A Study in Heredity.** By G. Archdall Reid, M.B., C.M., F.R.S.E., Author of "The Present Evolution of Man." Cloth. Pp. 293. Price, \$2.50. New York: Wm. Wood & Co., 1901.

## New Patents.

Patents of interest to physicians, December 31 and January 7:  
 690,091. Hernial truss. Karl Beyer, Cologne, Germany.  
 689,956. Car for disinfecting apparatus. Wm. H. Francis, Philadelphia.  
 689,957. Portable disinfecting apparatus. Wm. H. Francis, Philadelphia.  
 689,972. Syringe. Melchior R. Jamison, New York City.  
 690,154. Device for testing eyes. Christian F. Kuntlehner, Chelsen, Mich.  
 690,299. Fumigator. Joseph König, Guggenau, Germany.  
 689,987. Nursing nipple. David Pick, Salzburg, Austria-Hungary.  
 690,080. Producing quinate or urea. Otto Schutz and G. Dallmann, Gummersbach, Germany.  
 690,337. Disinfecting apparatus. Isidore W. Willets, Bloomsburg, Pa.  
 35,516. Design, nipple. Adolph McMurtre, New York City.  
 35,197. Design, invalid cushion. Christian W. Melnecke, Jersey City, N. J.  
 35,198. Design, blank for ear speculum blades. Hercules Pedretti, Philadelphia.  
 690,844. Combined springbed and invalid chair. James H. T. Edwards, Sanford, S. C.  
 690,724. Making acetone. Josef L. Hawliczek, Liverpool, Eng.  
 11,960. Re-issuance, salicylic ether of quinine. Fritz Hofmann, Elberfeld, Germany.  
 690,866. Apparatus for disinfecting sewer vaults. Wm. Martin, Chicago.  
 690,867. Compound for disinfecting purposes. Wm. Martin, Chicago.  
 690,527. Nasal distender. Wm. Moores, New York City.

690,759 Sterilizer for surgeons' use. Chas. E. Norton, Lewiston, Maine.  
 690,624 Hernial truss. Lucius A. Smith, Topeka, Kan.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 3 to 15, 1902, inclusive.

John M. Banister, major and surgeon, U. S. A., in addition to the duty with the troops on the transport *Buford*, required of him by former orders, is assigned to duty as transport surgeon on that transport during the voyage from New York City to the Philippine Islands.

Charles C. Billingsale, contract surgeon, from Westminster, Md., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Edward C. Carter, major and surgeon, U. S. A., member of a retiring board at Washington, D. C.

Louis W. Crumpton, major and surgeon, U. S. A., from San Francisco, Cal., to Washington, D. C., to report to the Surgeon-General of the Army for instructions.

Peter H. Egan, major and surgeon, U. S. A., from Fort Douglas, Utah, to San Francisco, Cal., en route for duty in the Division of the Philippines.

Robert C. Eve, contract surgeon, leave of absence for one month granted.

Henry M. Hall, contract surgeon, from the transport *Buford*, to duty on the transport *McClellan*, January 11.

Paul S. Halloran, lieutenant and asst. surgeon, U. S. A., leave of absence extended.

James R. Hallwood, contract surgeon, now at San Francisco, Cal., is relieved from further duty in the Division of the Philippines and assigned to temporary duty in the General Hospital, Presidio of San Francisco, Cal.

Richard W. Johnson, major and surgeon, U. S. A., from duty in the Division of the Philippines to Fort Douglas, Utah.

George B. Jones, contract surgeon, from Rushville, Ind., to San Francisco, Cal., en route for duty in the Division of the Philippines.

John S. Kulp, captain and asst. surgeon, U. S. A., attending surgeon and examiner of recruits at New York City, to report in person to the Surgeon-General of the Army on official business, and thereafter to return to his proper station.

William A. McVean, contract surgeon, from the General Hospital, Presidio of San Francisco, to Manila, P. I., for assignment in the Division of the Philippines.

James C. Merrill, major and surgeon, U. S. A., member of a retiring board at Washington, D. C.

Guy Stohr, contract surgeon, now at San Francisco, Cal., is relieved from further duty in the Division of the Philippines and assigned to temporary duty in the General Hospital, Presidio of San Francisco, Cal.

William J. Wakeman, major and surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., where on arrival he will report by telegraph to the Adjutant-General of the Army for orders.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ending January 18:

Asst. Surgeon J. H. Payne, detached from the *Isla de Cuba*, and ordered home.

Surgeon I. W. Kite, ordered to the Norfolk Navy Yard.

Surgeon H. T. Percy, detached from the Norfolk Navy Yard, and ordered to the Navy Yard, League Island, for duty with the Naval Recruiting Rendezvous, Philadelphia.

Surgeon W. F. Arnold, detached from the *New Orleans*, and ordered to Guam.

Asst. Surgeon J. T. Kennedy, detached from the *Brooklyn* and ordered to the *Hebe*.

Asst. Surgeon J. W. Rackus, detached from the *Brooklyn* and ordered to the *Princeton*.

Asst. Surgeon R. C. Holcomb, detached from the *Helena* and ordered to the *Maui*.

Asst. Surgeon R. W. Plummer, detached from the *Princeton* and ordered to the *New Orleans*.

P. A. Surgeon B. R. Ward, detached from the Boston Navy Yard and ordered to the *Constitution*.

P. A. Surgeon W. C. Bralsted, detached from recruiting duty and ordered to the Naval Hospital, New York.

P. A. Surgeon J. C. Pryor, detached from the Naval Hospital, New York, and ordered to the Naval Hospital, Newport, R. I.

### Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine Hospital Service for the seven days ended Jan. 16, 1902.

Surgeon A. H. Glennan, detailed to represent the service at the meeting of International Sanitary Conference at Havana, Cuba, February 15.

P. A. Surgeon G. M. Gutierrez, detailed to represent the service at meeting of International Sanitary Conference at Havana, Cuba, February 15.

Asst. Surgeon C. E. Decker, granted leave of absence, on account of sickness, for thirty days from January 15.

Asst. Surgeon C. H. Lavinder, bureau letter of January 2, 1902, granting leave of absence for two days, amended so that said leave shall be for one day only.

A. A. Surgeon R. C. Craig, to report to Surgeon F. W. Mead for duty.

A. A. Surgeon C. B. Sweeting, granted leave of absence for five days from January 23.

### AUTO-TOXEMIA AS A FACTOR IN THE NEUROSES.

GEORGE F. BUTLER, M.D.

Medical Superintendent, Alma Sanitarium, Alma, Mich.; Professor  
of Materia Medica and Therapeutics, College of  
Physicians and Surgeons.

CHICAGO.

The doctrine of auto-intoxication is a very old one; the central idea of the primitive conception survives in the term rheumatism, applied to a condition due to the auto-intoxication resultant on suboxidization. Many of the morbid states now regarded as auto-toxic were of old charged to rheums, as the products of rheumatism. Obesity and allied states were placed in the sixteenth century in the nosologic position they occupy to-day. In Sydenham's time the effects of these conditions were even better recognized than during the middle decades of the nineteenth century. Sydenham pointed out that suppressed gout (that is, gout without joint expression) exercised marked influence on the constitution. The body, he remarks, "is not the only sufferer and the dependent condition of the patient is not his worst misfortune. The mind suffers with the body, and which suffers most is hard to say. So much do mind and reason lose energy as energy is lost by the body, so susceptible and vacillating is the temper, such a trouble is the patient to others as well as himself, that a fit of gout is a fit of bad temper. To fear, anxiety and other passions, the gouty patient is a continual victim; whilst as the disease departs, the mind regains tranquillity." He also pointed out that gout affected the throat, heart and lungs as in asthma.

Upon the auto-intoxication doctrine was based the therapeutic principle underlying blood-letting. This aimed to remove the *materias morbi* and so replace blood by water as to carry on the circulation. The principle laid down by Sangrado (Le Sage's caricature of the phlebotomizer) was to drink water in great abundance as a universal menstruum which dissolves all kinds of salts. Plentiful bleedings and frequent draughts of water were to Sangrado the secret of health.

Auto-intoxication states existed to an enormous degree before the days of fresh winter vegetables, and formed the basis of most of what were called scorbutic disorders. For these reasons "spring cleaning," as it is called, still survives in popular medicine. In rural Italy the practice still obtains of bleeding in the spring and using water infusions of purgatives.

The practical adoption of the germ theory (which has hovered over the profession for two centuries) in the early eighties of the nineteenth century, turned atten-

tion, through discovery of the toxin, to the allied products formed in the system without bacterial action. Nearly simultaneous with this came the demarcation of neurasthenia by Beard, with the consequent study of fatigue and its results. Fatigue was found to produce auto-toxemia in two ways: First, by the direct products of nerve waste, and second, by the fatigue of the organs of sanguification and elimination from overwork after the loss of inhibitions, from central nerve tire. What were considered pathologic results, dependent on a specific lesion in a special location, were shown to be due to weakness of inhibito-motor centers, with resultant overwork of excito-motor neurons and the ultimate fatigue.

In this way occurred the fatigue fever pointed out by Vaughan and others. Fever, as Ott affirms, is primarily set up by an increase of heat production beyond that of heat dissipation, an agent from within or without deranging the harmony of the thermotaxic, thermogenetic and thermolytic apparatus by which in the initial stage the metabolism of the tissues is usually temporarily increased, this increment being greater than that generated upon a restricted amount of nutriment.

Once established, the fever continues, not from excessive production, but from an altered relation between heat production and heat dissipation. Fever is not a fire kept up by an excessive oxidation of the constituents of the economy. Heat production may be subnormal, yet the bodily temperature be at high fever heat. The thermotaxic centers of the brain so maintain balance between heat production and heat dissipation as to keep the temperature at 98.4 F. In fevers these thermotaxic centers are disordered so that the relation between heat production and heat dissipation being disturbed a higher temperature results. The peripheral endings of the sensory nerves influencing a thermolytic center are, therefore, important factors in heat regulation.

From disturbance of the thermic balance consequent to nerve shock or allied conditions, results the auto-intoxication state underlying saburral fever. This begins with loss of appetite, which may be gradual. The tongue is large, white and dirty; the mouth is clammy; the breath is fetid; constipation is habitual. The patient is languid, feeble, indisposed for work. The discomfort augments after each attempt to take food. Febrile paroxysms preceded by chills and followed by sweating often supervene. Sometimes jaundice and hepatic enlargement are present. Under the influence of overwork, emotion, exposure to cold, etc., arrest of digestion, nausea, vomiting, headache, chills and fever occur. In children and neurotics vertigo and convulsions often usher in and accompany the disease as an expression of the general toxic condition. There may be a week's fever nearly resembling a mild typhoid. Sometimes after one or more attacks a chill occurs, followed by

fever; profuse evacuations set in and convulsions rapidly ensue. There is generally constipation from the first. Even when there is diarrhea the natural evacuation may be insufficient for elimination.

The foregoing condition, which occurs generally without the fever, marks the onset of auto-toxemia and is an expression of the constitutional disturbance resultant on non-elimination. The hepatic involvement has a double expression. The liver has a poison-destroying, eliminatory function, and acts as a sanguiferent. Disturbance of either of these tends to produce auto-toxemia.

The various products produced through normal work are eliminated by various channels. Some are transformed in the alimentary canal into innocuous substances. Gases are eliminated by the lungs. Other compounds are intercepted and decomposed in the liver. Certain effete products are eliminated by the kidneys and skin. When any one of these excretories is interfered with in discharge of its functions the phenomena of auto-intoxication make their appearance. This is observed in certain affections of the alimentary system attended by headache, pallor, nosophobia, etc. These manifestations, the result of a chronic auto-intoxication, were not improperly attributed by the older writers to disturbance of hepatic functions.

The symptoms of auto-intoxication are often those of profound systemic depression, but they likewise, as already stated, present convulsive and exciting types. Nearly four decades ago Meynert suggested that epileptic attacks were due to an unstable nervous system acted on by the accumulation of a proteid toxic substance. This view was subsequently corroborated by the researches of Brueger, Bouchard, Féré and others on the toxic state of the urine antecedent to the epileptic state.

What is usually a congenital condition in the epileptic may be an acquired state from prolonged auto-toxemia, in which a sudden increase of auto-intoxication may excite centers whose inhibitions have already been weakened. This acquired predisposition is a temporary diathesis established in the manner described by Bouchard. Nerve reactions by corrupting for the moment nutrition not only produce the morbid opportunity, but may also modify nutrition in a lasting manner and develop diathesis. The acquired diathesis once established may become hereditarily transmissible in its etiology; be it in the individual or his ancestors, it has had for its origin the abnormal play of nerve reaction. Let a bad alimentary hygiene, cold and moisture, privation of air and light cause an infant to become lymphatic, and let the permanence of the same cause keep up the nutritive disorder which is designated as the scrofulous diathesis; or let a young man, by hygienic errors, by the abuse of the table, by protracted studies at night, by venereal excesses, by nervous shock, which may be the consequence of complete derangement of the mind as also of a jaded brain, develop this other nutritive disorder designated arthritism—in both cases each cell will have a tainted nutrition and will produce cells that maintain the same nutritive type. Among these cells are the generative elements; in their turn they give birth to the cells of a new being with nutritive activity similar to the individual which has begotten it. The acquired diathesis has become hereditary. It does not have for its cause in the descendants the vice of their own nerve reaction; in them, the diathetic state really arises from nerve perturbation experienced by their ancestors. There are, therefore, two factors to be reckoned with in auto-tox-

emia: the acquired diathesis and the effects on this of increased toxemia.

Relief from the ordinary effects of imperfect elimination is often very great so far as its expression in consciousness is concerned. In early life, as Havelock Ellis remarks, the emotions due to forced repression of excretions are frequently acute in the highest degree, and the joy of relief is correspondingly great. In adult life, on most occasions, these are pushed into the background of consciousness, partly by training, partly by the fact that involuntary muscular activity is less imperative in adult life, so that the psychic element in connection with ordinary excretions is almost negligible. In many cases, however, the balance of adult consciousness is so disturbed by irritations from auto-toxemia that relief from these produces a buoyancy out of proportion to the amount of elimination secured. In the adult the majority of functions cease to find expression other than in sub-conscious states.

Making up what is called consciousness are a number of clear conscious states, accompanied by others less clear and by physiologic states which, though not entering into consciousness, are even more potent than the conscious states. These last would be the first affected by auto-intoxication. The morbid irritations resulting therefrom obtrude on consciousness, producing anxiety and uncertainty. These morbid irritations of physiologic states produce the two great conditions ordinarily found as a result of auto-toxemia. The first is what the older clinicians called nervous adynamia and ascribed not only to the essential fevers, etc., but also to auto-toxemia.

From these two states, the conscious and the psychologic, the first an irritable weakness, the other a deep-seated constitutional neurosis, result the various conditions of temporary or protracted disorder charged to auto-toxemia. The two conditions are predisposing factors of almost distinct value. One type disturbs the balance of health so that it is easily upset and easily recovers. In the deeper type a secondary condition to auto-toxemia has been engendered, which, like all conditions influenced in their action by causes secondary to a great primary origin will not yield to treatment of this primary cause alone. This latter condition, like chronic nutritional disturbances, set up by syphilis, by the exanthemata, and by other diseases in which the nervous state or the nutritional disturbance remains long after the primary cause has disappeared, acts as a predisposing neurosis.

All these morbid states and prolonged auto-intoxication produce a protracted neuropathy with suspiciousal and anxious tendencies. This condition mimics all the chronic neuroses and is often taken for them, whence the frequent cures of conditions like tabes by quack systems and medical pretenders. To a certain extent the period of attack gives a complexion to the clinical picture. A very common type between 25 and 45 is a disorder mimicking locomotor ataxia and often accompanied by convulsive attacks. In such cases even physicians not unnaturally give an erroneous prognosis. Lightning-like pains of locomotor ataxia are simulated by temporary darting pains, partly of psychic origin. As the existing auto-toxic state aggravates any effect of eye strain and even produces these, in certain cases examination of the eyes often reveals conditions mistaken even by ophthalmologists for the preliminary stages of optic atrophy. As the reflexes are often as exaggerated in this condition as they are in the earlier stages of loco-

motor ataxia, an error in diagnosis is always possible.

The variations in the mental state of this class of cases requires but little to pass over into the confusional types of insanity, which, indeed, were the earliest directly charged to auto-intoxication. The most frequent type presented is that of acute confusional insanity. This was the case with those which Schroeder van der Kolk, decades ago, demonstrated to be due to fecal accumulation in the colon. In some cases melancholia is produced. The urine of these has been found to produce stupor and depression in animals. The urine from confusional cases produces stupid excitement and violence. Exceptionally emotional exaltation may occur, producing extravagant actions, thereby creating a suspicion of parietic dementia. A very frequent type produced by railroad travel aggravating auto-intoxication is a stupid hallucinatory violence, which disappears in a very few days after rest, the use of stimulant enemata and hypnotics. This type often occurs in persons of either sex traveling on their honeymoon.

In many cases charged to mental shock auto-intoxication is the dominant cause, which is often due to the inhibitory effect that mental shock has produced on the liver and kidneys, causing the latter to secrete only the clear, pale urine of nervous agitation. The cases of transitory frenzy, with their wild, brief, unremembered violence, charged to mental shocks, are really due to auto-toxemia. The gynecologic conditions ascribed by Goodell to nerve-tire are produced through intervention of auto-toxemia in the manner already described.

The most common symptoms of this form of nerve-tire are the very ones which lay tradition and dogmatic empiricism attribute to womb ailment. They are in the usual order of their frequency: Great weariness and more or less of nervousness and of wakefulness; inability to walk any distance, and a bearing-down feeling; then headache, napeache and backache. Next comes scant, painful, delayed or suppressed menstruation, cold feet, and an irritable bladder, general spinal and pelvic soreness, and pain in one or both ovaries. The woman, always tired, spends the day tired, goes to bed tired and wakes up tired, often, indeed, more so than when she fell asleep. She sighs a great deal, has low spirits, and often fancies that she will lose her mind. Her arms and legs become numb so frequently that she fears paralysis. The skin becomes dry, harsh and scurfy. Pigmentary deposits appear under the eyes, around the nipples, and on the chin and forehead. Blondes get mottled in complexion. Brunettes are disfigured by brown patches or by general bronzing. Sometimes the whole complexion changes to a darker hue, while a disfiguring growth of hair appears on the face. A physician, especially if the patient has backache, bearing-down feeling, an irritable bladder, and pain in the ovaries, is apt to hunt diligently for a uterine lesion. If one be found, no matter how trifling, he will attach to it undue importance and treat it heroically as the erring organ. If no visible or tangible disease of the sexual organs be discoverable, he will lay the blame on the invisible endometrium or on the unseeable ovary and continue the local treatment. In this connection it should be remembered that menstruation to a certain extent is eliminative, and that interference with it causes retention of toxic elements.

Even where the bowels seemingly move freely in constipated individuals elimination is very imperfect. The acid urine of these patients causes, as Spallaci long ago discovered, stupor, asthenia, tremor, tetanoid symptoms and hypothermia, followed by hyperthermia when inocu-

lated in animals. Improvement in elimination removes from the urine the factors producing these conditions. The urine of amenorrhoeic or dysmenorrhoeic women, not obviously suffering from constipation and having seemingly free movements of the bowels, present similar qualities. Mental states in women or nervous men are peculiarly apt to disturb primarily the genito-urinary apparatus and secondarily the hepatic and renal. Thus jealousy often evinces itself first in bladder disturbance, later in slight jaundice and symptoms resembling gall-stone colic.

These symptoms, according to Lepine, are very frequent in women and in nervous men after emotional disturbances. They are extreme expressions of auto-toxemia due to emotional disturbance. The fact is generally ignored but none the less clinically evident that nerve-tire and auto-intoxication work in a vicious circle. Here the influence of secondary casual factors, as often ignored in etiologic pathology, is evident. This is peculiarly obvious in nervous conditions due to errors of refraction and curable by proper glasses in an early stage. Here the influence of auto-intoxication in producing the headaches is shown in disappearance of the symptoms under treatment directed against the auto-intoxication alone. In a class of cases the supra-orbital headache of eye strain is combined with vertical and suboccipital headache. Here, although considerable astigmatism be present, all the headaches disappear under treatment for auto-toxemia. The underlying condition has not been removed, and, unless the astigmatism be treated, will soon cause auto-intoxication at the proper etiologic moment, attended with recurrence of the headaches.

The same is true of aural, rhinologic, laryngologic and pharyngeal states. Adenoids in children, for example, bring about constitutional disturbances, producing auto-toxemia through continued strain on the nervous organism. The nose, through its erectile tissue, having nerve relations to the erectile sexual systems, and, through the large extent of the olfactory nerve, may be irritated by the attempts at elimination through mucous membranes. This irritation, by exciting the nerves concerned, unduly increases the nerve-tire of the central nervous system and thereby the auto-intoxication. Pathologic sneezing is often an expression of this, and similar influences play a part in the auto-toxic laryngeal and pharyngeal vertiginous states so frequent in auto-toxemias. The irritations of these regions often occasion the undue cardiac stress which expresses itself in pseudo-anginas. Pelvic irritations of the female produce in a similar manner severe constitutional states. This is why women with severe pelvic disorder who have become insane recover without other treatment than removal from home surroundings and treatment of the auto-toxemia.

The predisposing cause, however, in these aural, laryngologic, rhinologic, pharyngeal and gynecologic conditions remain to set up recurrences of auto-toxemia and its consequences if untreated. Preparation for special procedures often imply treatment of auto-toxemia, which treatment predisposes remarkably to the benefits seemingly effected by operation. Very much of what is charged to reflex causes is really due to strain producing auto-toxemia little by little.

The pure type of auto-toxemia which underlies many of the so-called reflex states was recognized by the older clinicians as fecal anemia and treated on eliminative and roborant principles. The milder states resultant on auto-toxemia are generally of local expression like irri-

table bladder, various neuroses, unilateral headache, and neuralgic irritations about the gums and teeth, together with dermatoses like angioneurotic edema and hives, disordered rhino-laryngologic conditions, local fleeting pains, etc. The severe types may vary from fecal anemia to conditions simulating chlorosis, neurasthenia of the ordinary type and of types mimicking tabes, transitory frenzy, melancholia, acute confusional insanity, stupor, amnesia, emotionally exalted states, and sometimes epileptiform attacks resembling grave hysteria, but accompanied with partial or complete loss of consciousness.

One unpleasant and frequent mental state in otherwise logical auto-toxemias is nosophobia, or worry over the possibility of disease. This differs from hypochondria in the fact that the subject does not think he has a particular disease, but fears he may have. The irregular action of his organs resulting from auto-toxemia intrudes on his consciousness and causes a fear or uncertainty as to his actual state. That parietic dementia and tabes are often due to the toxin of syphilis is now generally admitted. The clinical history of some cases would indicate that auto-toxemia has here played its part more especially, as it has been demonstrated beyond cavil that temporary auto-toxic neuroses mimic these two great constitutional disorders. The fact is but too often forgotten that the law of periodicity of the nervous system gives a tendency of certain symptoms to recur from a slighter exciting cause. Hence, frequently recurring auto-intoxication causes that breakdown of the vasomotor balance which constitutes the underlying basis of tabes and parietic dementia.

Diagnosis in conditions of auto-intoxication is, therefore, not so simple as it first seems. Owing to the tendency of the neuroses with an underlying vasomotor factor to remit or assume temporary appearances of health, the distinction between the deep forms of auto-intoxication and these neuroses becomes at times difficult. This difficulty is intensified by the fact that auto-intoxication, in a hereditarily defective or acquired neuropathic constitution, may cause marked and decided symptoms of less augury than when found in a healthy constitution. Auto-intoxication occurring in puberty often temporarily initiates seemingly serious puberty neuroses and psychoses. The same is true of the climacteric end of the senile period. In all these cases the condition produced by auto-intoxication has the clinical tinge of the period in which it appears. This is why treatment directed to a change of environment and the habits of the individual so often produces favorable effects on seeming senile and climacteric breakdown.

The grave auto-intoxication resembling tabes and allied conditions are differentiated as a rule by the state of the reflexes as to absence of stupor, melancholia and acute confusional insanity, as well as amnesia, and differ little from the ordinary types except in their comparative quickness of response to treatment. This, however, is only a relative test, since in no case of these affections is auto-intoxication absent as an etiologic factor. The convulsive types of auto-intoxication differ from epilepsy in their infrequency and absence of recurrence. Practically the status of the auto-intoxicated is as brief as that of the epileptic is prolonged.

The therapeutics of auto-intoxication will depend on the type. In irritable weakness, while removal from surroundings is desirable for permanent recovery, much may be attained by regulation of diet, use of the mineral waters, regular, moderate exercise and massage, as well as hydrotherapy. Here, as in all cases of auto-intoxica-

tion, the great need of the system is water, and it should be amply supplied, whether in the form of mineral waters or ordinary water, or large quantities of milk. Purgatives require very careful adjustment; both aloetic and the cascara purgatives tend to produce congestion of the hemorrhoidal veins with resultant irritation. In old people salines must be used cautiously. In no small number of cases of irritable weakness a small dose of a mercurial followed by a morning saline acts rapidly and very beneficially in securing elimination, which is what is needed, not simple purgation. In the deeper type removal from home surroundings and conditions is imperatively indicated. In addition to dietetics, hydrotherapy, elimination and exercise, faradism and franklinization along the spine are often found necessary and valuable. The indication in this type for the use of water is no less imperative than in the first type. The patient, however, has an intense repugnance to water, as a rule, and to secure its use the physician will need much ingenuity.

One phase of auto-intoxication which has received less attention that it deserves is the pseudo-angina which so frequently occurs. Sometimes, albeit very rarely, death has occurred from this. This condition is due to the primarily increased inhibition of the heart, succeeded by increased power of the excitomotor ganglia of the heart with resultant irregular action. From this often results the emotional exaltation, depression and suspicious states found in auto-intoxication of brain and heart. It is readily comprehensible how these irregularities tend to increase each other. Independently of the condition just described, cardiac irregularities occur in auto-intoxication from arterial tension due to the character of the blood. Inevitable renal and hepatic disturbances occur, whence the temporary albuminuria and glycosuria.

The phenomena of arthritis deformans bear a marked resemblance to the trophic changes of tabes, and it is by no means improbable that they are sometimes due to the two states produced by auto-intoxication. The chronic type has so deranged the trophic mechanism that irritation changes result from the products of auto-intoxication. The influence of these factors can be shown experimentally by section of the sciatic nerve in rabbits and the injection of irritating material above the center of the body. As a result the side of the sciatic nerve section is attacked by arthritic changes like those of arthritis deformans.

## THE USES OF TUBERCULIN.\*

CHARLES DENISON, A.M., M.D.

DENVER, COLO.

When Koch had announced the discovery of tuberculin and the world was agog with expectations for the new cure of tuberculosis, this sign was said to have been posted upon the shop of an ambitious barber in Switzerland: "Corns treated and tuberculin given here." What was the conception of that barber as to the intricate nature of the remedy and the delicate shades of disease which were suited or unsuited to its use, it would be difficult to state. The case of some physicians who, under the assumed authority of professional proficiency, deal in borrowed criticisms of everything that pertains to the subject of this paper, is a little less inexplicable. A criticism to be of weight should be based upon a reasonably complete personal knowledge.

\* Read before the Congress on Tuberculosis, Medical Section, held in London, July, 1901.

If I can succeed in clearing away any of the clouds which befall this subject my object in presenting the following remarks upon my own experience will have been accomplished.

We will divide the uses of tuberculin into two parts: 1, diagnostic, and 2, immunizing.

The diagnostic powers of tuberculin are now generally recognized and much better understood than the immunizing. However, we shall learn that they are not so very different from each other as the separate purposes of their employment would seem to signify. The diagnostic effect seems to depend upon what comes out of the bacilli, i. e., the quality that resides in the culture fluid in which they have grown, while the immunizing property seems to center in the bodies of the germs, as Koch determined with his new tuberculin (R).

This diagnostic effect has thus far constituted the chief use of tuberculin, i. e., the glycerin extract originally termed "lymph." The method of manufacture is to concentrate the glycerin culture fluid at ordinary boiling temperature down to one-tenth its original bulk, after which it is filtered through porcelain. It thus contains various substances, namely, a combination of toxins and proteids capable of producing intense reaction in living tubercular tissue. It includes 50 per cent. glycerin—beef extract—beef peptones and salts, and small quantities of the specific tubercle bacilli proteids which are liberated during the growth of the culture and during the process of the boiling and concentration of the fluid.

As to the chemical constituents of this reactionary material, we will let very good authorities explain. Drs. Vaughan and Cooley<sup>1</sup> say: "In fact, it may be safely said that in no case has the chemical nature of the essential toxin of any of the pathogenic bacteria been shown."

They instance Buchner's investigations on pus-producing substances in bacterial cells, stating his conclusions that there is nothing in the whole category of decomposition products, caused by bacteria, to account for the phenomena of general infectious diseases, but that the cause of these must be looked for in the albuminates of the bacterial cell itself, and that in some cases, at least, these poisons are only set free on the death and dissolution of the bacterial cell. By this theory he explains the fact that suppuration may be caused by dead cultures of germs which, when living, have not the pyogenic property.

As to the *modus operandi* of this reactionary effect we are not quite so much in the dark. It seems that there is a specific stimulation of the defensive cells of the body with reference especially to infected areas, and in proportion to the sensitiveness of the nervous system, the blood supply and advanced degree of said infection. The circulation of the blood in the lungs, being proportionately more active for a given area (than for any as large portion of the periphery of the body), the most sensitive and active effects may be looked for in pulmonary tissue. The increase of the number and flocking to the affected area of leucocytes and phagocytes constitute the specific effect which has not yet been similarly shown to occur with the use of any other substances, such as cinnamic acid, oil of cloves or peppermint, nuclein, etc., which are capable of increasing general leucocytosis.

This effect may be so great, with too far advanced infection, as to produce a choking off of nearly destroyed tissue; a necrotic process is thus carried to an extreme, and grave problems of elimination are forced upon the

animal economy as a result. It is not, however, these extreme effects with which we intend to deal. They are always and especially to be avoided.

Hueppe<sup>2</sup> says: "When a local disturbance occurs as a consequence of paracytic invasion, then a reactive inflammation with the formation of a limiting wall of leucocytes takes place, an event that must be considered as a natural healing process and that often ends in recovery." "Ribbert asserts that this surrounding mantle of white blood corpuscles prevents nutrient material and oxygen from reaching the bacteria, but perhaps also the white blood corpuscles disintegrate and so become chemically active in the way pointed out by Hankin."

All of this serves to explain how intimately associated are the diagnostic and the immunity effects of tuberculin. In fact, the latter process, the therapeutic effect, is diagnostic all the way through, so relative is it to the degree and to the results of infection, and so dependent is it upon the resistance and environment of the human body. Diagnostic proficiency, then, of a discriminating and far-reaching kind, is the key to success in handling this remedy. Observance of technique is also essential.

The size of the dose hypodermically given for diagnostic purposes varies with different experimenters who give different reasons for the course they pursue. Some prefer to give very small initial doses with intervals of two or three days between. The liability is that they will create a tolerance and so miss the mark, the temperature rise or reaction they are after. Others prefer to give a single large dose similar to the plan pursued by veterinarians with cattle. The danger here is the possibility of getting too severe a reaction for the case in hand. The suspicions or expectations of physicians, as regards the possible existence of infection, varies so greatly that some would use this test when as little or less than one milligram would cause a reaction in an adult. In such cases I think we ought to be able to determine the diagnosis without the test. So the diagnostic dose has varied, I should say, from one to thirty milligrams (or of a 1 per cent. solution, approximately 2 to 45 minims) of the crude tuberculin—Koch. I prefer myself to follow a middle course between the above extremes and start with what I expect may be an effective dose and daily increase it. Let it be cumulative if it must be. We thus approach the reactionary point and learn much of the degree of infection. Each morning give a dose approximately double that given the previous day till you reach 20 or 30 milligrams, if you do not get conclusive evidence of infection before that time. The size of the initial dose must depend upon the physician's suspicions of infection, the age, sex and susceptibility of the subject. The individual sensitiveness of certain patients to this reaction is an important phase of this matter. I have obtained reaction to one milligram in a male adult and had to reach 20 mgs. before getting the same evidence in a female, with both of whom the after-course and treatment apparently proved the correctness of the diagnosis.

Therefore, the initial dose for a child or susceptible young woman, I would place at from 1 mg. glycerin extract of tuberculin,<sup>3</sup> up to 5 or 6 mgs. (or 9 or 10 minims) for an adult male, and each day nearly double the previous day's dose, as before described. If the patient has kept a temperature record (taken at say 9 a. m., 1, 4 and 8 p. m.), for two or three days previously,

3. Standardized, as obtained in America, through Victor Koechl Co., N. Y., or the Bacterio-Therapeutic Laboratory at Asheville, N. C.

1. The Bacterial Toxins. Drs. Victor C. Vaughan and Thomas B. Cooley, JOURNAL A. M. A., Feb. 23, 1901.

any habitual rise can be accounted for. I prefer a morning hour for the test injections, because if an evening hour is chosen a sudden rise of temperature may be missed during sleep. This rise may come in four hours, if the tubercular lesion is centrally located in the lungs, or at a much later time if located in other organs or in the joints. If it happens to be encapsulated in far off glandular structure, the response may be slower still, very likely manifesting itself the following day. Any suspicious but not definitely conclusive reaction may indicate the wisdom of waiting over a day or two, and then a larger dose will determine the genuineness of the effect.

We are by no means limited to the temperature curve in determining that a reaction has taken place. A temperature rise does not uniformly occur, and it may be subordinate to the systemic effect. The latter is much like the sensation of the oncoming of an attack of la grippe. In fact, it is sometimes difficult to eliminate la grippe if that disease happens at the time to be prevalent. Besides the systemic reaction there is the local effect in even slightly affected lung tissue, perhaps previously undetected, and one which occurs earlier there than in an advanced stage of localized disease in the same lung. This is the most helpful diagnostic indication to be obtained from the test. But one must have the discriminating ear and stethoscope to appreciate it. This, I think, is a result of the specific action of the tuberculin, stimulating as it does leucocytosis at the point of injury. The effort at repair being accompanied by a certain amount of infiltration and congestion of the slightly affected tissues, produces a higher pitched-breath sound than normal, more puerile and bronchovesicular, which is quite characteristic. The local reaction is also a possible guide to the direct method of immunization, which will be considered later on.

We have not time here to discuss at length the claim that other diseases, as syphilis and leprosy, likewise respond to this tuberculin test. The uncertainty of the relation of these diseases to tuberculosis, and the very general existence of the tubercular dyscrasia (or latent tuberculosis) in the human family, shrouds the whole question in doubt, warranting a verdict for the test; that is, where the test works affirmatively it is nearly always safe to assume at least latent tuberculosis exists.

These uncertainties (the difference in dose and technique employed by different observers) may account for much of the discrepancy in positive results obtained, which amount to from 60 to 100 per cent.,<sup>4</sup> positive or affirmative diagnoses. My own cases, including quite suspicious cases, but only such as it was deemed could not otherwise be proved to be tubercular, have given about 90 per cent. positive results. I think only 5 out of 46 were shown to be negative.

The test is of interest and very helpful to us in forestalling active tuberculosis at the very time when a cure is possible. It, as Petrusky asserts, has "the power of disclosing the presence of unsuspected foci of tuberculosis," which makes it a peculiarly valuable diagnostic resource. It is safe and no harm need come from its cautious employment.<sup>5</sup>

4. J. M. Anders: JOURNAL A. M. A., Jan. 12, 1901. "The Diagnosis and Treatment of the Prebacillary Stage of Pulmonary Tuberculosis;" 3683 cases in which this tuberculin test has been made by different physicians with an average of 78 per cent. positive reactions.

5. Petrusky: Vortraege zur Tuberculosis-bekampfung, Leipzig, 1900. Writer cites the discovery by Schreiber "that newborn children during the first week of life did not once react to this diagnostic test, to which a great number were subjected." This should not only strengthen our confidence in the reliability of this diagnostic method, but also weaken the claims of those who believe in the possible congenital transmission of the disease.

#### IMMUNITY-PRODUCING QUALITY.

The subject of the immunity-producing quality in tuberculin is next in order. The need of discovering this protective principle and separating it from the crude tuberculin has been appreciated, but the problem has not been an easy one. It remains to be learned whether all has been done that is possible. Koch thought he had reached the goal in his new tuberculin—R. But the crudeness of this necessarily doubtfully perfect emulsion—though we admit it to be a simple substance made from the bodies of the bacilli—did not favorably impress cautious experimenters. However, some of the healing or immunizing property seemed to have been determined, as above expressed by Buchner, "in the albuminates of the bacterial cell itself." We will return to the consideration of this remedial agent after describing the various preparations.

Lack of time and the desire not to confound the indirect with the direct tuberculin method, must be my excuse for not here fully considering the former—the antitubercular sera.

I am aware that the possibility of transmitted tuberculin being proved to be the therapeutic principle in these animal serums may give color to the claim that they and the direct tuberculins should all be considered under one head. Yet the uncertainty of these sera from their lack of standardization and from the variety of elements which have to be included in their manufacture is objectionable. The amount and virility of the toxin administered to an animal, and the time and resistance required to change it to a possible antitoxin—as it is supposed to be done in diphtheria—are questionable elements, which require too much abject faith in the commercial side of this matter to gain full confidence. In view of the questionable composition of an antitubercle serum it might be well to heed Ferdinand Hueppe's warning when he says of the antidiphtheric serum: "There is serious disappointment in store for us if we do not succeed in ridding ourselves at once of the fallacy regarding the absolute harmlessness of the antitoxins." Until we know exactly what we have in these sera, let us not confound the serum with the tuberculin treatment. We can at least assume the two to be different and not interchangeable.

After the crude tuberculin, or glycerin extract, we have Koch's tuberculin (R), previously mentioned.

Then we have Kleb's tuberculoceidin, one of the first efforts to improve on the crude tuberculin,<sup>6</sup> but it is of questionable utility because probably too much of the toxin is eliminated.

*Antiphthisin* (Kleb's) is very similar, except instead of being produced from tuberculin it is obtained from the culture fluid upon which the tubercle bacilli have been grown, without the application of boiling heat for concentration. This was thought to preserve in the material an immunizing property in the proteid which power would have been destroyed by boiling, otherwise this preparation is treated and standardized the same as tuberculoceidin.

6. It is made from tuberculin by precipitating with an alkaloidal reagent (usually the sodic iodid of bismuth) throwing down many of the albuminoids which are contained in the culture fluids; the precipitate is filtered out and then the filtrate is further treated with an alkali, for the purpose of precipitating the reagent used in the first place, and is again filtered. The clear fluid is then treated with absolute alcohol—obtaining another precipitate which is collected upon a filter dried and redissolved in distilled water. Standardization to 1 per cent., this liquid contains proteids from the beef extract and peptones; it is, however, free from glycerin and from salts, contains also some of the specific products from the germ the same as does tuberculin, and as much, if none has been lost in the process of purification.

*Tuberculinum purificatum* (von Ruck), unlike the two previous preparations, is made from the whole culture fluid with the tubercle bacilli grown therein included. The object being to extract more of the tubercle bacilli proteids, it is boiled at a temperature of 120 to 130 F. in vacuo for a long time, say for six weeks or two months. The tubercle bacilli are then filtered out and the filtrate is treated and standardized, the same as in the preparation of tuberculoceidin and antiphthisin. This preparation then differs from the other two in that it contains more of the specific tubercle bacilli toxins. It is not so much of a departure from the crude extract as they are, and it undoubtedly contains considerable of the principle Koch found to be immunizing in his tuberculin (R). This purified tuberculin, besides being an improvement on the crude article, has this advantage over the next greater improvement made by von Ruck in his *watery extract*, namely, that it costs about one-tenth as much, and therefore should be suitable for use in practice among the poor. Koch's tuberculin (R) undoubtedly contained the choice toxin immunizing property. Six years ago a substitute in the form of a clear liquid extract was suggested by me to Dr. von Ruck as an equivalent, which should be thoroughly filtered and standardized. The object was to get rid of the unpurified emulsion quality in the tuberculin R. Dr. von Ruck has well accomplished this in his watery extract, and gives his technique of manufacture as follows: "No culture fluid at all is used—only the tubercle bacilli obtained from full virulent cultures. These are filtered out of the culture fluid, and while on the filter are washed with distilled water to thoroughly remove the same. Then all moisture is removed by drying in vacuo, when they are powdered as finely as possible in an agate mortar. After this they are treated with sulphuric ether for the extraction of fats, and this treatment is continued till fats are no longer obtained. Thereafter the tubercle bacilli are again dried and powdered as before, when they are placed in a large glass container and pure sterilized distilled water is added. This glass container is then placed in a continued water bath with a temperature between 120 and 130 F. for a period of two or three months and occasionally agitated, when the fluid is syphoned off and filtered through porcelain. This fluid is then examined for proteids (and, if necessary, is concentrated) and standardized to 1 per cent., which represents the 'No. 100' solution. The result is that this fluid contains only the pure tubercle proteids (soluble in water) and nothing else. The whole process, including the germ culture and the after-testing on guinea-pigs, takes about a year for its completion. Experimental work has shown that the final product is the undoubted toxin of the tubercle bacillus, and that it contains immunizing and curative properties."

Thus it is apparent that the study of the tuberculins during the ten or more years since Koch put out his first product has been fruitful in the evolution of a remedy which approaches perfection.

My own experience favors this conclusion, and as there has been no time that I have not been at work with some one or two of these preparations, I can conscientiously say that the last is preferable to all the others.

The accompanying table, completed Feb. 20, 1901, gives the general results in 213 undoubted tuberculous cases, being probably one-fourth those seen by me, and all of those I have treated with any form of tuberculin in the ten years named, excluding those not under that

treatment longer than a month, also excluding those treated for diagnostic purposes only. It may, however, be said that the gravity of the disease in these cases was sufficient to seem to demand that some additional help for them should be found beyond the usual methods of treatment; I mean even beyond the combination treatment which I always deem essential, embracing climate, hygiene, physical exercise, outdoor life, attention to alimentation, appropriate inhaling methods, etc. The complications and conditions indicated gravity, which was shown by the stage of disease at commencement of treatment. Of the 213 cases reported in the table 50 were in the first, 45 in the second, and 118 in the third stage. Note, too, that the results are carried forward to as late a date as possible, so that the favorable outcome bears evidence of the staying qualities of the immunity produced, even admitting that it was partial or incomplete. To summarize: Of 57 patients treated with crude tuberculin, eight to ten years ago, 17 or 30 per cent. are now known to be living; of 94 patients, treated with the purified forms of tuberculin (tuberculoceidin, antiphthisin and tuberculinum purificatum) from four to seven years ago, 30 or 32 per cent. are living in good condition; while of 45 watery extract cases, 28 or 62 per cent. are living in apparent immunity.

TABLE OF RESULTS OF SPECIFIC TREATMENT.

Roman numerals=Stage of disease. Av. yrs.=Years known to be alive after commencement of treatment.

| Specific remedy used.                                | Now or recently known to have been in good health. | Now supposed to be living.              | Whereabouts unknown; possibly dead.    | Dead; cause in part known.              | General Results.                               |   |  |
|--|--|---|--|---|--|---|--|
|  |  |   |  |   | Disease thoroughly arrested or seemingly cured | Much benefited, immunity increased, life prolonged. | Retrgraded or died; possibly of intercurrent causes. |
| Tuberculin (Koch) 57 cases reported.                 | I. 7<br>II. 3<br>III. 7<br>Av. yr., 8½             | I. 5<br>II. 4<br>III. 9<br>Av. yr., 2½  | I. 0<br>II. 1<br>III. 7<br>Av. yr., 2  | I. 0<br>II. 4<br>III. 10<br>Av. yr., 2½ | 18   | 23  | 16   |
| Tuberculoceidin (Klebs) 21 cases reported.           | I. 3<br>II. 2<br>III. 1<br>Av. yr., 7              | I. 1<br>II. 2<br>III. 3<br>Av. yr., 2½  | I. 0<br>II. 0<br>III. 5<br>Av. yr., 1½ | I. 0<br>II. 0<br>III. 4<br>Av. yr., 1   | 6  | 10  | 5  |
| Antiphthisin (Klebs) 47 cases reported.              | I. 6<br>II. 4<br>III. 6<br>Av. yr., 5              | I. 3<br>II. 3<br>III. 11<br>Av. yr., 1¾ | I. 0<br>II. 1<br>III. 7<br>Av. yr., 1½ | I. 0<br>II. 1<br>III. 5<br>Av. yr., 2½  | 17   | 19  | 11   |

| Antiphthisin serum, T. R. (Fisch) 11 cases reported. | I. 1<br>II. 2<br>III. 1<br>Av. yr., 3½             | I. 0<br>II. 1<br>III. 1<br>Av. yr., 2   | I. 0<br>II. 1<br>III. 1<br>Av. yr., 7½ | I. 0<br>II. 1<br>III. 1<br>Av. yr., 1   | 3  | 5   | 3  |
| Oxy-tuberculin (Hirschfelder) 3 cases reported.      | I. 0<br>II. 0<br>III. 0<br>Av. yr., 2              | I. 0<br>II. 1<br>III. 0<br>Av. yr., 2   | I. 0<br>II. 0<br>III. 1<br>Av. yr., 1  | I. 0<br>II. 0<br>III. 1<br>Av. yr., ½   | 0  | 1   | 2  |
| Tuberculin, purif. (von Ruck) 26 cases reported.     | I. 5<br>II. 1<br>III. 2<br>Av. yr., 3¾             | I. 3<br>II. 2<br>III. 4<br>Av. yr., 1½  | I. 0<br>II. 0<br>III. 1<br>Av. yr., 1  | I. 0<br>II. 0<br>III. 8<br>Av. yr., 1   | 9  | 9   | 8  |
| Watery extract (von Ruck) 45 cases reported.         | I. 13<br>II. 6<br>III. 9<br>Av. yr., 1½            | I. 2<br>II. 2<br>III. 5<br>Av. yr., 1¼  | I. 0<br>II. 1<br>III. 2*<br>Av. yr., 1 | I. 1<br>II. 0<br>III. 4*<br>Av. yr., ¾  | 18   | 22  | 5+   |

Reduced to percentages, and lumping similar methods for comparison, we have the following table: The first

\* None of these were completed cases: 3 died of pneumonia, 1 of grippe, 1 from results of dissipation, and all some months after treatment.

+ Previous column should rightly have benefit of 3 of these.

column of figures denotes "Disease arrested or apparent cures;" the second, "Much improved—immunity relatively increased;" the third, "Retrograded or died from various causes."

TABLE OF COMPARISONS BY PERCENTAGES.

|   |    |    |    |                                       |
|---|----|----|----|---------------------------------------|
| Tuberculin  | 32 | 40 | 28 | Approximately 1 yrs. since treatment. |
| Tuberculo-bacillin, antiphthi-<br>sin, tuberculinum purifi-<br>catum. | 33 | 40 | 27 | Approximately 1 yrs. since treatment. |
| Asses' serum, antiphthi-<br>sin.                                      | 39 | 40 | 30 | Approximately 3 yrs. since treatment. |
| Watery extract  | 40 | 49 | 11 | Approximately 1 yr. since treatment.  |

For comparison, I also introduce herein Dr. von Ruck's lately tabulated "Comparative table of results."

|   | Cases reported. | Percent. | Reconv. | Improv. |
|---|-----------------|----------|---------|---------|
| Treated without specific remedies                               | 816             | 12.1     | 31.0    |         |
| Treated with Koch's tuberculin                                  | 379             | 35.5     | 37.5    |         |
| Treated with antiphthism and tu-<br>berculoidin                 | 182             | 32.5     | 56.8    |         |
| Treated with purified tuberculin (von<br>Ruck)                  | 166             | 43.4     | 39.2    |         |
| Treated with watery extract of tu-<br>bercle bacilli (von Ruck) | 303             | 56.1     | 33.7    |         |

I leave these tabulations to speak for themselves, for I wish to devote any remaining time allotted me for the discussion of the *modus operandi* of this immunizing process.

Ferdinand Hueppe\* says: "By undergoing a disease the predisposition to that disease is removed and converted into its opposite immunity. In no case can anything appear in the form of disease which was not previously present in the body as a predisposition; external forces are able merely to make this predisposition apparent."

Applying this fundamental statement to tuberculosis we may be able to successfully answer the prevalent objection to this immunizing use of tuberculin. We can thus show that it is pre-eminently a natural process, and safe when intelligently used.

The objection referred to is based upon fear which, in turn, is grounded upon a false conception of the nature of this dyscrasic disease. The fear is that by the hypodermic injections we are introducing a toxin into a system already burdened by an excess of the same poison. This is a misconception of the facts. The truth is the toxin which is in the system is not appreciated by it in the way of being absorbed into the circulation. The whole nature of the process is to oppose such a result. Absorption is impossible because the toxin is stowed away in the germs in non-vascular tissue. Tuberculosis is not the destructive disease we picture it, at least not until it has reached and passed the breaking-down stage. Till then it is a building up, defensive process, i. e., during the pre-tubercular and infiltration stages. When this dyscrasia, which is an acquired fault of our civilization (more fully considered in my paper on "Devitalized-Air Toxemia, a Prime Cause of Tuberculosis") becomes a germ disease, whether by a possible auto-genesis or by transplantation from without the affected body, then the toxins are formed and centered in the bodies of the germs. If, in the beginning of their formation, these toxins could be appreciated by the system the disease would be auto-curative, if I may coin the term, and the tolerance or purification of the system,

which we know occurs slowly under the present régime, would happen quickly; or if rapidly an unsurmountable amount of toxin were generated the end would also come quickly, as it does in diphtheria. But it is not that way in tuberculosis; the leucocytes and phagocytes begin their defensive warfare and stop absorption in the beginning of the trouble. They build their walls of non-vascular tissue around the germs—which encapsulation constitutes what we know as "tubercles"—and absorption thereafter is almost impossible. Not only this much hindrance to absorption is the rule, but the bacilli themselves are enshrouded in a coating of fat which still further prevents their disintegration even should they be set loose in the blood current. It is only by intricate chemical procedure that these enveloping fats, or fats and cellulose, can be dissolved away from the germs.

Not only is there this much of natural defense against the appreciation of the toxins by absorption in the commencement of tuberculosis, but all the way through the same relief from absorption is characteristic of Nature's provision. When it comes to the breaking up, and when necrotic processes and ulceration show that the non-vascular tissue has reached its limit and its death has commenced, then the vomica in the lungs and profuse expectoration of bacilli and mixed infection can still be looked upon as a part of Nature's effort at self-defense. Degeneration and breaking down occur, but there is not enough absorption of the toxin to stimulate Nature's antitoxic power, and finally there is not enough antitoxic power remaining in the exhausted system, not enough leucocytes and phagocytes left, to be stimulated.

What is needed is to aid Nature's defense when the cells are there to fight and when there is not too much for those that are there to do. There are many ways of stimulating this defense, viz., climate, exercise and good feeding each can do wonders, all of which tend to nullify the injury of rebreathed or devitalized air. But for specific stimulation, when Nature has no proper direction given her defensive cells, choose the toxin from the nucleus of the germ isolated from extraneous fats and not heated so much in the making as to lessen or destroy its immunizing power. Petrusky is satisfied with Koch's new tuberculin R, but he appears not to have known of von Ruck's Watery Extract, a more refined and better standardized product. Choose only such cases for the treatment as will favorably stand the specific stimulation. Be constantly hedging, by under rather than by full dosage, against overaction. The direction laid down by Petrusky is not bad. He says: "We should aim to produce a strong local, but weak general reaction." But do not expect any immediate healing effect upon necrotic tubercular tissue, concealed tubercular abscesses, ulcerating cavities, or any other manifestation of tuberculosis where the circulation of the blood does not reach. Such conditions are obstacles to any treatment whatever and will be favorably influenced very slowly if at all. This may mean a large concession to our average inability to accurately state what is taking place in concealed areas. Especially does extra caution need to be taken when tuberculosis is complicated with active pleurisy, with la grippe or other toxemia, as measles, etc. Better wait for the subsidence of any such conditions before proceeding with the specific treatment.

Dividing, as does Hueppe, the kinds of immunity into: 1, natural; 2, artificial, and 3, toleration, it is the third we are seeking to strengthen by our specific medication. By the other two, parasites are prevented from entering the body, but by this third kind the body has

\* From "Clinical Report," Winyah Sanitarium, Asheville, N. C. 8. Op. cit., p. 249.

acquired the power of "paralyzing" the toxins of the germs. One of the best proofs possible that very little of the toxins are absorbed during the course of tuberculosis, is that this toleration immunity acts as it does. There is no time in this disease, from the earliest period of tubercle formation till years of the process have passed, when patients are not most sensitive to tubercle bacilli toxins. Yet experience shows that that sensitiveness can be gradually overcome and tremendous doses of toxins finally given without any reaction whatever. This would not be so if the germs were giving up these same peculiar toxins through absorption. The acquirement of this protective immunity takes time, for it must come about through slow and laborious intervention of the body cells. As Hueppe says: "The body cells, because of their relatively great independence of varying conditions of nutrition, are able to cling to their inherited or acquired characteristics." The resistance to their action is, of course, relative to the extent and results of the existing toxemia. In incipient cases of tuberculosis tolerative immunity to the extent of a cure may be obtained by this specific method in two or three months, while in others past the beginning of the ulcerating stage, the fight may have to be prolonged at times for two or three years with all the possible outside helps we can muster to our aid. Hueppe's reasoning seems to show that it is the active (protective) immunity as by the direct method which we need rather than the transient passive kind, as by the indirect method. "It is the organism of the host—the cellular tissues of the human being—that reacts toward the stimulus of those bacteria or bacterial proteids or toxins with which we endeavor to heighten the resistance toward parasites and parasitic poisons." The cells eliminate this strange proteid as soon as possible.

It is for this reason that passive immunity is not lasting. The chronic nature of tuberculosis, with its incapsulation of toxic products, and its protective walls of hypertrophied and infiltrated tissues, indicates the lesser application of the transient passive (indirect serums) as compared with the staying active (direct) method of immunization. Hueppe says: "In general, however, the defensive reaction which is provoked by isopathic or specific stimuli is the stronger and more persistent, and hence often appears peculiar in kind." It is peculiar in kind and is found (as Koch, Buchner, Vaughan, von Ruck and others have surmised or shown) in the proteids from the bodies of the germs themselves. "Gamelia, Hueppe, and afterwards H. Buchner, were led to the discovery that the 'specific' poisonous substances found outside the parasites in the culture fluids were not identical with the protective substance occurring in the disease germs or their metabolic products."<sup>9</sup> Petrusky, then, was wrong in his statement "that nothing will be gained by the search for new forms of tuberculin." So have men high in authority said that there was no use looking for any specific whatever in tuberculosis, for they said there were none to be found. Yet I, for one, like to think that there is more in store for us to be discovered in reference to tuberculosis than all we now know.

9. Hueppe: *Op. cit.*, p. 308.

**Dermatomyiasis.**—L. Freund reports the case of a child with impetiginous eczema, extremely malodorous. The putrid odor was finally traced to two patches on the skull, and on removing the scabs, a nest of maggots was found beneath. 32 in all. They had eaten the periosteum down to the bone.—*Weiner Med. Woch.*, December 21.

## THE IMPORTANCE OF HEREDITY AS A CAUSE OF INSANITY.\*

ARTHUR MCGUGAN, B.Sc., M.D.

Late Assistant Physician, Michigan Asylum for the Insane, Kalamazoo, Mich.; Professor of Psychiatry in the State University of Colorado.

DENVER, COLO.

Freed from the trammeling influence of all metaphysical association and disencumbered of such ideas or expressions as "soul," "sublime intelligence," "spirit," "cosmic consciousness," etc., the study of that particular form of energy to which we refer as mind or mental action grows considerably less perplexing, and permits of speculation and observation from the same point of view as does the investigation of other functions of the same class of cell structure and as we proceed in our contemplation of mind as simply a function of matter, we are struck by the resemblance of the manner and degree in which its variations depend upon variations in form and arrangement of its particular protoplasm, to the manner in which other functions are modified by similar changes in the structures upon which they are dependent.

Now, of all variations in cell structure how clear it should be to us that this one of a retrograde character depending upon faulty development of, or degenerative potentiality in, the parent cell, and which we call an hereditary defect is no exception to the rule. It is a fact that has long been disguised, however, by misleading statistical information and hidden in a maze of metaphysical and quasi-scientific theories.

If it be established then, as our major premise, that this defective function we call insanity is a variation from the normal due to heredity, then it is obvious that the anatomic defect in the corresponding structure, upon which the defective function depends, must also be due to heredity. If this is so, then insanity is not primarily a disease, as we are commonly taught, but is an inherited defect and therefore in the individual incurable, although its manifestations may be controlled and modified. This much being granted, there are many other conclusions which follow logically and which will be presented later.

We must, first of all, come to an agreement as to just what we mean by heredity. A few brief references to the opinions of some of the leading authorities will serve to show the necessity for an understanding of some sort.

The view most widely held by medical men in general, and also by authorities on this subject, among whom I might mention Régis,<sup>1</sup> Charles Mercier<sup>2</sup> and Darwin,<sup>3</sup> is that the long-established law, "like begets like," holds good for morbid states as well as normal ones. Some observers refute the statement entirely, claiming that nature seeks to avoid a transmission of morbid states and will, wherever possible, return to the normal or physiologic plane. They hold that heredity is nothing more than disease tendency. There are shades of difference in the various views included in this class; for instance, some go so far as to say that certain organs, the nervous system among them, are susceptible to the same disease that affected the same organs in progenitors. Others again maintain that disease tendency in the offspring simply means a generally defective organism that may express itself in a susceptibility to disease of any kind and in any organ.

A third view still to be considered is one, which with the first, rejects the idea of tendency to a transmission

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

of morbid states, and yet does not admit with the second, that although morbid states are not usually transmitted, disease tendency may be, but holds that by heredity as applied to insanity we mean that the reproductive element of either the male or female carries with it merely an impaired potentiality. Its protoplasm is deficient in reproductive strength, and being thus defective will produce a defective organism. Kraepelin is the only prominent exponent of this theory.

In recent works upon insanity the subject of heredity is lightly touched upon, and in some, particularly the latest edition of Clouston<sup>4</sup> and also the second edition of Bevan Lewis,<sup>5</sup> no statement of the nature of heredity is presented. Weismann's work on the germ plasm, published in 1893, deals more particularly with transmission of acquired characteristics of a normal type, and does not aid us materially in the solution of this question. T. H. Kellogg,<sup>6</sup> formerly superintendent of the Willard State Hospital, gives a very good summing up of heredity. The relation of heredity to insanity is given and its modifications extensively discussed, but the author does not take any definite stand, presenting the conclusions that have been drawn from statistics of the past and contenting himself with the statement that "it is the tendency and not the disease which is inherited, and that it is instability of the nervous system and susceptibility to mental disorders which descend from insane parents to the offspring."

Régis presents a very clear statement of his position on this question, from which I have abstracted the following: "Heredity is without contradiction the most powerful and important of all the causes of insanity. It is an original predisposition to mental alienation transmitted to children from their parents." He calls attention further to the fact that this predisposition may be not merely mental alienation in the ancestors, but there are related diseases such as eccentricity, neurosis, alcoholism, certain diathesis, consanguinity, etc. He admits along with Marcé that we may find some antecedents in nine-tenths of all cases.

The excellent article by Charles Mercier in Tuke's "Dictionary of Psychological Medicine" contains the following sentence: "The law of the direct transmission of qualities is simply that the offspring tends to inherit every attribute of both parents; inheritance is the rule, non-inheritance the anomaly." The inference from this statement and other expressions in the article is that morbid tendencies, at least, if not morbid states as well as healthy ones can be transmitted. He also devotes considerable discussion to the question of the law of consanguinity, which he calls the second law of heredity and which he states as follows: "The quality of the organization of the offspring depends on the suitability of the parents to each other," and proceeding from this premise, he advances various conclusions showing that insanity and allied defects are due, in many cases, to non-observance of this law. I think that we may take his article in its entirety as representing quite fairly the attitude on this subject of the British school of alienists.

An article refreshing in its clearness and brevity is that by Dr. Peterson<sup>7</sup> of New York appearing in the text-book published by Drs. Church and Peterson last year. He calls attention, as do very few authorities, to the necessity for investigating the presence in the family not only of insanity, but of the hereditary equivalents, and states that "it is an unstable nervous organism that is

inherited in both neurosis and psychosis." He calls attention also to the faulty manner in which the statistics of heredity are gathered, and presents for example the statement prepared by the Lunacy Commissioners of England and Wales, showing that in 136,478 admissions to the asylums their hereditary influence ascertained was but 20.5 per cent. He is inclined to agree with Mercier on the principles of heredity, and also, I take it, upon the nature of hereditary transmission, particularly in regard to the law of consanguinity.

Of journal literature bearing upon this subject I find very little of value in the form of clear statements on the nature of insane heredity or of its degree of prevalence.

In the files of the *Journal of Mental Science* I find reference to the paper of J. F. Bristoe,<sup>8</sup> read at the annual meeting of the Medico-Psychological Association held in London in 1896, in which he gives as his opinion that 90 per cent. of the insane have insane heredity. This statement is striking from the simple fact that thus far he has stood almost alone in his assumption. No mention is made of any observations, however, that would substantiate his position. There are also one or two fairly good reviews of Weismann's doctrine, but nothing that is of much benefit to us. Volume No. 41 contains a review of an article by Charles Féré<sup>9</sup> of Paris, published in 1894, in which attention is called to the fact "that in heredity that which is really transmitted are errors of nutrition, producing different effects during the embryological period, according to the stage in which they occur. Errors of development cause a morbid predisposition. Thus, hereditary troubles or circumstances of evolution bring progressive destruction of the characteristics of the race, that is, they induce degeneration." He makes two divisions of hereditary tendency in nervous diseases, one which he calls insane heredity and one neurotic heredity.

One of the best of the earlier contributions to the study of heredity in insanity is that of the late Dr. Gray<sup>10</sup> of Utica. He takes exception to such views as those of Mercier and Régis, and quite successfully attacks the theory that morbid states as well as normal attributes are transmitted. I select a paragraph which states his position very clearly. He says: "What I wish to combat is the notion of the direct transmissibility of disease as such; the monstrous figment of scientific pessimism that the abnormalities and lesions of the human organism can acquire in such persistent and stable character as its own *virida vis* itself, that nature puts a destructive force on an even race with the constructive in any of her operations—an idea which ought to be contrary to any philosophic system of evolution itself. If all that is claimed for morbid heredity be true it would be a cumulative process which must eventually swamp the vital energies of the world. It seems philosophically absurd to assume that a force so opposed to organic life can so seat itself in the constitution of an organism as to perpetuate itself by that organism's generating power. Nature rejects or eliminates the taint of death. No sooner do the decaying elements enter the earth than they are transformed into life-giving agents and that which is 'corruptible puts on incorruption.' The earth itself is not more surely the purifier of all corruption than is the stream of human vitality which shows its recuperative tendency, casting out and eliminating the elements that are hostile to its own existence and welfare."

Much more might be added to illustrate the diversity of views upon this question, but it is not necessary

and probably this much is uncalled for, as you all must be aware of these differences in opinion and feel, as I do, the need of a clear statement to which the most of us can subscribe. I shall return to this later and take up here, the other point of difference—degree of prevalence.

On this subject also we find a wide variety of expression. The proportion of insanity considered to be due to hereditary causes varies from 13 per cent., as reported by some of the English asylums, up to about 70 per cent., as held by some of our latest German authorities, particularly Kraepelin.<sup>11</sup> The average given by the annual reports of various institutions of this country varies between 25 and 40 per cent. I need not take the time here to discuss the reasons for this, they are so apparent. Simply, first of all, the failure to agree on the question, "What is heredity?" and second, differences in methods of history-taking.

In the first year or two of my connection with asylum practice, two things in particular made a very profound impression on me. The first was the fact that nearly every insane person presented stigmata of degeneration, or at least, deviations from the normal both as to face and figure, and also that in many of their relatives who came to visit them these peculiarities could be noticed. The other was the disinclination of patient's relatives to admit freely the existence of insanity, inebriety, eccentricity, nervousness, consumption or allied conditions in the family, and also that in many of the cases already on record in the asylum having "no heredity" written under the head of "family history" subsequent inquiry made of disinterested persons elicited information showing the presence of perhaps several cases in that particular instance. These observations naturally led to extensive reference to available authorities, and the astonishing differences of opinion alluded to above were found. It seemed to me at once, and is now quite plain, that these figures are grossly misleading, and pernicious in their ultimate effect.

After several years of observation in which a careful record of hundreds of cases has been made, I have come to the conclusion that there is a family history of defective nervous health in perhaps 95 per cent. or more of all cases admitted, at least from such a district as that in which I have gathered my facts, and I shall present here for your consideration the results shown by the analysis of the family history in 200 individuals, 100 of them being consecutive cases in which the writer has conducted the history-taking, and the other as a control observation, the analysis of the family health of 100 sane individuals of supposed normal organization.

In the 100 consecutive cases of the insane there were 31 showing direct insane heredity, 35 showing collateral insane heredity, a total of 66 per cent. Of the remainder, 14 showed direct or collateral neurotic heredity, this including epilepsy, inebriety, the so-called nervous types, etc., and 8 gave a history of direct or collateral consumption, the total being 89 out of 100. Then, there are many instances where there are combinations of these conditions, for example, there were 11 cases in which neurotic and insane heredity were combined, 12 in which consumptive heredity and insanity were combined, 7 in which consumptive and neurotic heredity were combined, and 4 in which there was insane, consumptive and neurotic heredity, so that in the 100 cases presented for analysis there was insane heredity in 66, neurotic in 38, and consumption in 31. In 3 cases out of the 100 there was a history of parents being first cousins.

Of the 11 cases not included in the analysis, there being in the family history none of the conditions tabulated, one came of a family in which 6 died before the age of 12 months was reached and two more were still-born—the father, it is said, died of apoplexy. Two more presented very decided stigmata, both physical and mental, and the father of one died under 40, apoplexy being given as cause of death. Three more presented family history in which cancer or apoplexy had existed. There remain then just 5 cases out of the 100 with family history perfectly clear of all these conditions, and of these 5 none have prominent stigmata, 4 are well and one is still under treatment. In the tabulation of all these cases note was made of the patient's age, sex, social state, form of psychosis, and result of treatment, but as these items do not affect my conclusions I need not refer to them here.

Turning now to the analysis of the 100 presumably normal individuals we find no direct insane heredity, but 3 cases of collateral insane heredity, 14 of direct and collateral neurotic heredity and 22 of direct or collateral consumptive heredity. Consumptive heredity was combined with neurotic heredity in 7 cases, so that the total number with consumptive heredity was 30. The parents were not related in any case. This observation of the family history of the normal individual was made upon asylum nurses and attendants to the number of 150, 100 consecutive cases being taken for analysis.

On finding, in our investigation of insane heredity, the great discrepancy between our results and that of other observers, it was thought that possibly if inquiry regarding the family health of the normal individual were made to the searching extent that was made in the ones of the insane individual it might be found that even in the family of the sane, conditions resulting in insanity or degeneracy might be found to a surprising extent. The asylum attendant was regarded as a proper subject on which to make this observation, as he has been reared under the same geographical conditions and social influences as are the patients. The possible difficulty of getting accurate and unreserved returns was at once realized, and in order to meet this we sent printed forms to each attendant arranged in such a way that he could indicate the health of each individual in his family, both ancestral and collateral members, simply by making check-marks opposite points indicated. The instructions read that names need not be signed, nor any indication of the reporter's identity be given. We have every reason to believe that the reports made are truthful and that as far as possible they are complete, certainly as complete as the histories of the insane individuals presented in this analysis. It is fair to assume, perhaps, that the asylum nurse or attendant is superior in nervous organization to the average man or woman of our district, as a high standard of health in our probationers is insisted upon. I do not know though that this should weaken the force of deductions made from the comparison of their family health with that of the insane, for they represent the very class in which insanity does not develop. It is so extremely seldom that a relation of an attendant or an ex-attendant is admitted as a patient that it is a matter for especial comment.

Let us return now to the question of the nature of hereditary influence. This is something that does not as yet admit of conclusive ocular demonstration, but can be narrowed to a small compass by inductive and deductive processes. I shall content myself for the present by offering for discussion what is scarcely more than a tentative statement of the view I hold and which in

some respects is an expansion of the idea embraced in the last of the three theories alluded to above.

1. All defectives must necessarily have derived a defective something from their ancestry.

2. This is probably a protoplasmic defect in one or both of the reproductive elements and is not necessarily a disease or even a disease tendency, but may consist merely in a lack of inherent power to grow to a normal or full development. Both disease and disease tendency may be transmitted in utero from the mother but such is not hereditary.

3. The defect in the reproductive cell depends upon a deficient or deranged innervation in the parental organism, which in its turn is due to hereditary defect or acquired derangement of various sorts, but all acting on the cell through the nervous system of the parent.

This conception of heredity would, of course, extend the list of conditions that may result in insanity, or other defective states of the nervous system. In its greatest breadth it means that any condition operating upon the development of the parental cell, and which has the effect of impairing, even in the normal individual, its nutrition and so its potentiality, will result in a defective ovum or spermatozoon and so in defective progeny. It would include all such conditions as overwork, dyspepsia and other serious defects in assimilation, wasting disease, neurasthenia, abuse of the sexual function, and in fact, a list so long that we can not discuss it all here. It rejects the idea that morbid states are transmitted through the cell itself, questions the possibility of morbid tendencies being so transmitted, and maintains in short that the various manifestations resulting from what we call heredity are due simply to a *weakened* reproductive element. This view is based principally on the following thoughts:

1. The overwhelming evidence that Nature everywhere seeks to eliminate the abnormal, and that as stated by Dr. Gray, the assumption that morbid states could be transmitted per ovum would be at variance with the fundamental principle of evolution itself. On the other hand, the theory that the defect in the fertilized cell is simply a lack of developmental force is quite compatible with established biological facts and is antagonistic to none.

2. If we assumed that by hereditary defect was meant that certain organs of the descendant were impaired by reason of corresponding defects in the same organs of ascendants, we should have to prove that certain portions of the blastodermic protoplasm developed into certain organs, or, in other words, that differentiation anticipated segmentation. Now we know that this is not true, because differentiation is largely a matter of position of the cell, for experiments with ova of both vertebrate and invertebrate show, for instance, that the nervous system can be made to develop from either the upper or the lower surface of the egg, depending on which side is up; then how could any particular section of its protoplasm serve as the object of hereditary disease selection? Embryology furnishes further proof along this line that can be adduced if necessary.

3. A careful analytical study of stigmata of degeneration shows that in the various deviations from the normal there is very seldom any marked resemblance to corresponding features in the parent, but on the contrary a marked deviation from the ancestral type is seen. We do find, however, on every hand evidence to support the theory I have offered, for what are stigmata of degeneration but deficiencies and inequalities in development combined with occasional reversions to lower type, all of

which are the logical results of impaired potency of the germinal cell.

4. If the defect is one of impaired force, then the result of this impairment will be seen at the point most remote embryologically from the generating force. This point is the neuron; here we find the highest type of cell development. There is no further cell division, no further differentiation.<sup>1</sup>

Before proceeding to my conclusions, let me say that they, of course, depend not on the analysis of the 200 cases presented, but upon many times that number, the time at my disposal not permitting more extensive tabulation. I must admit that facts I have gathered from the study of degeneracy have also influenced me not a little.

If you grant me that heredity, as I have defined it, is the fundamental cause of 90 or 95 per cent. of insanity, then:

1. Insanity is not a disease, but a congenital defect, the manifestations of which appear from time to time as irritation is applied. There are some very apparent exceptions to this, consisting of a small percentage of cases in which physical or mental stress is so great as to be in itself sufficient.

2. If insanity is such a condition, then it is, in the individual, practically incurable and must be met, if met at all, before it has existence. In other words, we must not wait for the appearance of the individual before we set in operation our therapeutic measures. Let me explain here that I do not call a remission of a year or so, or indeed several years, a cure. It might be remarked that on this theory there are derangements of many organs of which the same might be said regarding recovery, so that it is simply a juggling of terms. It must be remembered, though, that a disorder affecting, for instance, the cortex of the kidney may be compensated for by other tissue and its results are scarcely seen for years, while a disorder of much less extent in the cortex of the brain will in a short time wreck a life completely.

3. If this deduction as to curability in the individual be true then the question of the treatment of the acute stages of insanity sinks into insignificance beside the great problem of controlling heredity.

The State of New York is much engaged at present with the question of psychopathic wards. We have just had an appropriation in Michigan for such a ward at the University Hospital. These are much needed additions to the teaching armamentarium and will be welcomed as such by all, but the trend of editorial expression regarding this is in emphasis of another phase of the question, viz., the possibility of some world-startling discovery as to the cause and hence the cure of insanity. Now, this is, to put it mildly, ill-advised. As a student, I was taught just such nonsense, and I entered the field of psychiatry filled with vague ideas of "reflex eye strain," "reflex pelvic irritation," possible microbial origin in the cerebrospinal fluid, and a host of other things equally unimportant—but of heredity very little. Those of us who are living with the insane recognize these and other exciting causes of insanity—recognize them at their true value and treat them. The care of the acute case is comparatively a simple problem. At the Michigan Asylum at Kalamazoo we are enthusiastic in our efforts for the restoration of the restorable, and it happens to be my privilege to care for this class. I can not lose sight of the fact, however, that many of the cases we proudly dismiss as cured return to us, in a few years at the outside, after having bestowed upon the community several more to take, in a decade or two

hence, the places in the asylum once occupied by their progenitors.

4. If my major premise be correct it defines the limits in certain directions of the function of the pathological laboratory as an adjunct to the study of the etiology of insanity. For several years pathologists, neurologists and others have been telling us that every asylum should have a laboratory for the purpose of working out the cause or causes of insanity, and many asylums have, in consequence, established laboratories where both time and money is spent in a frantic effort to be doing "pathological work," and which in many instances has no bearing upon the great problem. Now, it does not seem to me that the microscope can reveal to us the cause of insanity if we already know it. The pathological anatomist can in time give us as good a description of a neuron congenitally defective, as he does now of a diseased one, and that, of course, will be interesting. There is, in fact, considerable work being done in this line at present. But the usefulness of the asylum laboratory. I am inclined to think, will be found to lie in the direction of investigation of deranged metabolism and of errors in the process of elimination, this including the nature and extent of its effects upon nerve tissue, rather than in the consideration of deterioration changes dependent upon dementia.

5. Finally, if the facts so far presented have not inflated values, our work upon this question is very plainly cut out for us. It is already evident that of the two questions—prevention of insanity and the care of the insane—the writer attaches chief importance to the former. The consideration of prophylaxis, although not coming within the scope of my paper as indicated by the title, still must follow naturally and the matter seems so urgent in its demands upon our attention that I can not refrain from outlining one or two suggestions.

The increase of insanity can be regulated both by legislation and education, and the feebleness of effort being made at present along either line does not do justice to the severity of the case. The question of legislative control is a problem far too knotty for me, and I shall dismiss it briefly.

No doubt there is a large class of defectives that is fit only for legislative control; it can not be reached by reason, but I think it is safe to assume in general that when legislative efforts of the prohibitionists have made such little headway against the craving for alcohol, all similar efforts directed against the control of a much stronger passion will be found correspondingly more futile. The question of legalized mutilation comes in properly here, and I mention it simply for the purpose of inviting discussion, having upon the subject no clearly defined idea myself.

When we come, however, to the question of education, there is much to say and more to do. Little is being accomplished, not very much attempted, with this remedy, and it is the one of all that will in the end be found efficient. There are several lines of action that might be suggested.

1. The asylum or hospital for the insane should be for its district the source of constant effort towards the promulgation of truth regarding the influence upon progeny of heredity and of errors in living. This effort should be in the form of popular articles in the papers of the district, not at infrequent intervals, but appearing regularly, and in such form as to command attention and thought. The medical officers of the asylum should be as actively employed as possible in what I might call medical missionary work throughout the district. Not

a month should go by without a popular lecture delivered in some portion of the district by an asylum man.

2. A more important place should be accorded the study of insanity in our medical colleges. The teacher should be, in every case, a man who has had previous asylum experience of, at least, four or five years, and should have at his disposal for clinical instruction a department for the insane such as is now proposed in many localities, under the name of psychopathic wards.

3. The general practitioner could be reached frequently and effectively by papers presented in the meetings of local medical societies. It is very seldom, indeed, that we ever notice any paper upon this subject at such gatherings, and those that are presented deal with treatment rather than with etiology.

The subject of prophylaxis is, of course, too broad a one to be adequately presented at this time, and in conclusion I have only to say, that not until we recognize more generally the fact that insanity is but one of many symptoms, that the disorder itself is defective organization and that prophylactic control is the only control, will any *real* progress in psychiatry be made.

#### DISCUSSION.

DR. EDWARD E. MAYER, Pittsburg—I wish to enter a decided protest against some of the essayist's views. It seems to me that if we viewed the subject from his standpoint, we would relegate the treatment of insanity and the treatment of the insane to where it stood fifty years ago. I am entirely opposed to such nihilism and pessimism, especially in this aspect of medicine. I believe, of course, that heredity is the most potent cause of insanity, but as far as I know it is not the only factor. It seems to me that environmental causes deserve a little consideration. Hereditary causes are often sought for too persistently; physicians attempt to trace cause to effect through generations widely separated and ignore the other factors which are in play. If we agree with Dr. McGugan's views, then the superintendents of our insane asylums should simply be regarded as boardinghouse-keepers, and we must say to 95 per cent. of the insane: "You were unfortunate in your birth and we can do nothing for you." I believe that at least some of the acquired psychoses are curable and do not harm the descendants. Furthermore, I think the statement that heredity is the cause of insanity in 95 per cent. of cases is not in accordance with the consensus of opinion on this subject; that proportion is too high. Authors vary in their statistics between 4 and 90 per cent. in giving heredity as the cause of insanity. Statistics of course are deceiving and the results depend upon the views of the statistician. It seems to me also that to neglect such factors as environment, civilization, syphilis, alcoholism, and toxic conditions requires some explanation.

DR. RICHARD DEWEY, Wauwatosa, Wis.—Recently, in this state, an attempt was made by the legislature to prevent the marriage of any one who was afflicted with insanity, epilepsy and certain other diseases. Such laws at least call the attention of the people to the importance of these matters, even if but little is accomplished by them in a practical way, and that it is to be feared is their chief utility. People palpably affected are not likely to try marriage, and others can not be prevented.

DR. T. D. CROTHERS, Hartford—From my experience with persons who are addicted to the use of alcohol and drugs, I

have become firmly convinced that heredity is not only a potent factor in these conditions, but also in insanity. I believe that in a large proportion of these cases there is a strong predisposition toward insanity, or alcoholism and the abuse of drugs which is acquired from their forefathers. I believe this is present in from 60 to 70 per cent. In the cases of alcoholism, which I have collected, the habit is distinctly traceable to one or both parents in this proportion.

DR. C. A. DREW, Massachusetts.—If I understand the essayist correctly, he advocates educational methods for the correction of the hereditary elements of insanity, and general hospital methods—the rational treatment of all abnormal states of the blood and derangement of the different organs—for the correction of contributing factors. In this I heartily agree with him. I do not agree with one of the speakers that the paper contained any statement advocating a return to old methods—or hopeless methods. It is well to look the facts squarely in the face, and the facts concerning heredity which Dr. McGaugan has collected and presented in his paper harmonize, I believe, with the observation and experience of those who have most carefully studied the causative relation of degenerating neurons and insanity.

DR. H. S. DRAYTON, New York City.—To a certain extent I agree entirely with the reader of the paper, but I am not with him in all his conclusions. I think the discussion of this subject will prove somewhat analogous to that on criminality as carried on in the conventions held in Europe during the past eight or ten years. Some years ago the school of Benedict and Lombroso was in the ascendant regarding the status of the criminal, the proposition that a man was a criminal by reason of his brain organism being enunciated by that school. In the more recent discussions, however, I have noticed a decided change in the attitude of anthropologists, and the point has been accentuated by Monodvier and others that after all it was not so much the heredity of the individual as the environment in which he was brought up from childhood that had to do with the criminal evolution in conduct and life. I am willing to accept heredity as a prime factor in many conditions of our mortal career, but I think that environment should be regarded as an equally potent factor, and even more potent in determining action on any given occasion. I believe in giving the individual, however low born, a chance for improving so that the beneficial effects of education and a proper milieu may offset the drawbacks of his birth and childhood's surroundings, and so favor his evolution toward good. That this evolution is possible has been demonstrated by the results obtained in many institutions in Europe and in this country. The authorities of the Burnham Farm at Albany, which was established for the purpose of reclaiming reckless and vagabond boys, have been encouraged by the happy effect of the training given there. Many that were deemed incurable were found amenable to discipline and instructions that are judiciously administered.

DR. JOSEPH E. RUTSOM, Nevada, Mo.—We are often asked what is the cause of insanity, and as the result of eight years' study of this question I have come to regard heredity as a very important factor. "Like produces like," not only in the animal kingdom, but also among human beings. This is something we must all admit. In getting the history of an insane patient, I have frequently noticed a disposition on the part of friends or other members of the family to hide or distort the real facts regarding the commencement of other cases of mental trouble in the family. This should be borne in mind in connection with the statistics on this point. I regard insanity as a mental manifestation of a physical disorder in persons who have an inherited predisposition toward mental diseases. In such individuals the soil is ready for the seed.

DR. F. SAYRE PRYOR, Philadelphia.—Last year this Section was besought to uphold certain members of the profession in New York in their petition that the New York State Pathological Institute should not be discontinued. We upheld them in their request, and no one can underestimate the value of the work done in New York and in other laboratories throughout the country. While their services are most valuable in connection with asylum work, I think that physiologic chem-

istry is really paramount, and it is in that field that the greatest discoveries in connection with insanity will be found.

THE CHAIRMAN, DR. TOMLINSON.—The most of the work in the pathology of insanity has been done by neurologists, and they have paid too much attention to the morbid histology of the brain and too little to the natural history of mental disturbance. In 1895, in Boston, I read a paper before the American Neurological Association on "The Transmutation, Coexistence and Concurrence of Insanity and Phthisis," and gave the statistics derived from a study of the patients in the hospital at St. Peter. The statistics went to show that our patients who died from phthisis were the children of insane or neurotic parents; while those among our patients who were the children of the tuberculous did not die from phthisis. In some families there was a concurrence of insanity and phthisis, and in some patients coexistence of both forms of degeneration. I think that the problem of heredity has been beloged in discussion by the widely different conceptions of what is meant by the term, and this confusion exists especially in the relation of heredity to insanity. If development teaches us anything, it is that heredity really means some condition existing in the parents which results in bringing into the world an individual of limited potentiality, and this unequal limitation may involve a particular structure or those which are similar in function. The frequent involvement of the nervous system, even where the weakness in the parents involved some other part of the organism, is probably due to the well-known law of degeneration, that those structures which are the most highly developed and complicated are the first to be involved. There must be something besides the syphilis, alcoholism, other disease or traumatism to produce insanity, and that something is the limited cerebral potentiality of the individual. It does not necessarily follow that he must be the child of insane parents. He may have been born of syphilitic, epileptic, gouty or tuberculous parents, who, on account of the impaired vitality which results from the presence of these diathetic conditions, have given birth to a child of limited cerebral potentiality. The children of the insane are, as a rule, unstable, while the children of those who are the victims of diathetic conditions are defective. These latter may become actively insane, but usually progressively degenerate. The former may never be insane, but tuberculous instead.

DR. ARTHUR MCGUGAN, Kalamazoo, Mich.—Replying to Dr. Mayer, I admit that I may seem pessimistic, but we must face facts as we find them. I firmly believe that heredity is the fundamental cause of insanity in 90 per cent. of our cases, or even more, and I wish to emphasize this point for the proportion reported is not "estimated," guessed at, or borrowed from the observation of others, but is based upon the results of my own long continued and carefully recorded observations. It is not to be assumed with Dr. Mayer that, were my conclusions accepted we must retrograde, but rather that we shall look forward to new and broader fields, for progress must always rest upon truth, not sentiment. Neither is it to be assumed that insanity not being a condition presenting hope of permanent cure we should relax our efforts in the care of the individual. I wish to state in this connection that we have at the asylum with which I am connected and on my service, a special hospital building for recent cases where all the so-called "sanitarium methods" of treatment are provided for and used; indeed, we are most enthusiastic in our efforts for the restoration of these unfortunates, but upon the reappearance of normal mental action we do not felicitate ourselves that we have produced a cure; it is simply a remission. Realizing then so clearly that cures are few and far between, the same management of the patient is directed to be carried on at his home after discharge or parole is ordered with special reference to the prolonging of the remission. I quite agree with Dr. Drayton in regard to the importance of environmental influence upon the children of degenerates. The restoration of the family line to a normal plane would require probably as many generations as it took to reduce it to its present abnormal condition. This is a practical application of the study of heredity and is an expression of the frankest optimism.

## INCIPIENT AMYOTROPHIC LATERAL SCLEROSIS, WITH RECOVERY.

BRACHIAL NEURITIS, ANGINA PECTORIS AND EPILEPSY  
FROM ELECTRICAL INJURY.—TRAUMATIC NEURITIS  
AND PERSISTENT BRACHIAL NEURALGIA FROM  
HYPODERMIC INJECTION.\*

LEO M. CRAFTS, B.L., M.D.

Dean and Professor of Nervous Diseases in Hamline University;  
Visiting Neurologist to the Minneapolis City Hospital,  
Asbury Methodist Hospital, Etc.

MINNEAPOLIS.

The following cases have been selected because of unusual conditions obtaining in each which make them instructive and of sufficient value to warrant their presentation.

### INCIPIENT AMYOTROPHIC LATERAL SCLEROSIS WITH RECOVERY.

The family history shows a pronounced neuropathic taint both important and interesting as an hereditary element in causation. On the mother's side a great grand aunt was confined in an asylum. The grandmother had much rheumatism with heart complications and was very "nervous." A great grand uncle was similarly afflicted, and the grandfather died of apoplexy. An uncle when young had some sort of attacks of unconsciousness, apparently epileptiform in type, and is now nervously unstable. An aunt is subject to frequent fainting attacks. One cousin has had chorea and two others are nervously excitable. His mother has suffered much from vertex headaches, and following his birth, for a long time, had distressing feelings that different parts of her body were very large. She has much trouble swallowing hard foods. The patient's oldest sister had hydrocephalus, was very precocious but peculiar, and died of diphtheric paralysis of the throat.

The subject of this report first came under observation in January, 1899, and was under control for eighteen months. He was the weaker of twins, developed slowly and did not walk till he was two and a half. He was bright, learned to talk quickly, but was peculiar and hard to manage. When first seen he was 16 years old, tall and slight, having grown very rapidly. About two months previously wasting had been noticed in the muscles of the left hand between the thumb and forefinger, and soon after this on the back of the hand.

When first seen there was pronounced loss of substance in the adductors of the left thumb with deep excavation, and also marked depressions between the first and second metacarpal bones. The thenar and hypothenar eminences were distinctly flattened, as was also the entire palm, and the thumb was approximated to the first finger. The hand was weak and tired easily. There was no history of injury, and no complaint of numbness, but there had been very slight pain in the palm of the hand. There was no tenderness along the nerve trunks of the arm and no sensory disturbances of any sort. The grip was weak, the hand slightly tremulous. All the tendon and periosteal reflexes of the left arm were much increased, those of the right arm were somewhat more active than usual, but there was no muscular involvement. The muscles of the left forearm showed some loss and measured one-half inch less than the right. The hand had a pale and trophic look. Fibrillation was not observed, and the reaction of degeneration was not present, although there was apparently quantitative diminution in electrical response over

the affected muscles. Musculature was still normal in the right arm and both legs. The patellar reflex was somewhat increased, more on the left; there was no clonus.

The patient's head was strikingly peculiar in shape, very high above the ears, the forehead flat and the antero-posterior diameter short, the measurements being as follows: Vertical height, meatus to crown, 6 inches; antero-posterior diameter,  $7\frac{1}{4}$  inches; transverse diameter,  $5\frac{7}{8}$  inches; circumference,  $21\frac{1}{2}$  inches. These peculiarities are probably of only relative value, indicative of general congenital defects.

As this was an absolutely typical syndrome of amyotrophic sclerosis, an entirely unfavorable prognosis was given, but treatment was begun at once with the galvanic current, long sittings, thirty to forty minutes, three times a week, with a current of moderate strength, 8 to 15 milliamperes. The nitrate of strychnia,  $\frac{1}{30}$  grain, three times a day, was given with short interruptions for over a year, and hot salt baths with massage three times a week. Free feeding was instituted and rest and exercise regulated, avoiding all fatigue.

For a time the condition progressed, then, after becoming apparently stationary, distinct improvement was manifest. The volume of the interossei returned first, the adductors of the thumb began to fill out, and the thenar and antithenar eminences and palm following gradually. Improvement continued to complete restoration of muscular volume and strength, which it reached in about fifteen months from the beginning of treatment. He has also become robust and developed a solid physique. All treatment was discontinued more than a year ago; the hand has remained entirely well, and recovery may fairly be considered complete.

All authorities agree on a uniformly unfavorable prognosis in amyotrophic lateral sclerosis. Strümpell, alone, quoting Seligmann, says that in very rare cases in young subjects the process may be arrested. Accurate knowledge of the pathology and clinical grouping of the degenerative processes of the nervous system is still too recent for dogmatic conclusions as to possible results, and up to the present we have little exact data on the causes which lead to their development. Such cases as the above help to point leading factors in the direction of heredity and faulty and lowered nutrition. This boy inherited a weak nervous system, which proved unequal to the strain of rapid physical development, and began to give way. The clear indication is for measures calculated to stimulate and improve nutrition generally, and especially of the nerve structures, cell and fiber that have begun to break down, at the same time removing all sources of fatigue. Recent results by various observers in this direction point toward a distinctly improved prognosis in degenerative processes of the nervous system and may well claim our closest investigation.

### BRACHIAL NEURITIS, EPILEPSY AND ANGINA PECTORIS FROM INJURY BY ELECTRICITY.

A young man of fine physique and an athlete, a motor-man on a street railway, was taking a disabled car to the repair shops. The rheostat would not work, and the current had to be controlled by the cut-out. His hand came in contact with exposed metal while the other hand was on the brake wheel, his body closing the circuit. He hung suspended from the handle of the cut-out, unconscious, while the car moved about a thousand feet, part of the distance being on an upgrade. The jar of the car running over a switch and the bending of the handle broke the circuit, allowing him to fall to the floor, when he came to consciousness. Getting to his feet he found

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

the left arm powerless and without feeling, two large burns on the left thumb and several smaller ones on the right hand; his head ached severely. About eight hours after the accident intense pain began in the left arm and side, which was continuous for several weeks, almost entirely preventing sleep, with entire loss of muscular power in the arm, slight flexor power then showing in fingers and elbow. The pain in the side at times, on exertion, developed spasmodic attacks, shooting through the chest to the back, radiating down the arm, and excruciating in intensity. Seizures with loss of consciousness also developed on the second day following the accident, with brief tonic and clonic spasm, voiding of urine, biting of the cheek, and sequent stupor for an hour or two. He was losing flesh and dull mentally; had deficient memory, little sleep and poor appetite.

Physical examination showed a well-developed physique, dull and fixed facial expression, face flushing easily, left arm carried partially flexed and held stiffly, fingers partly flexed, hand cool, somewhat cyanosed and mottled in appearance. There was slight power or motion only in hand and arm, and all passive motion caused severe pain, accompanied by spasmodic contraction of the muscles. There was increased irritability of muscle bodies to reflex stimulation and tenderness along the nerve trunks of the arm.

Measurements showed the left forearm and upper arm  $\frac{3}{4}$  inch smaller than the right, over the middle of the deltoid 1 inch smaller, crest of the deltoid  $1\frac{1}{4}$  inches, and the left chest  $1\frac{3}{8}$  inches less than the right. There was also loss of sensation, both to touch and to temperature and pain throughout the left arm, the left side of the body to the median line including the side of the head and face, except the ear, and a small area about the wing of the nose and the upper lip. It extended down to the hip, and a paresthesia continued over the upper third of the thigh, on the outer side. The loss in muscular volume about the shoulder and arm was very apparent on observation. There was distinct fibrillation, more especially noticeable in the deltoid and triceps. The pupils were normal. The field of vision showed moderate limitation. There was no incoordination and no involvement of the lower extremities.

Slight improvement occurred in the power of motion in the left arm after three or four months. The anesthesia was a little less profound; the pain in the arm improved decidedly, but the attacks of spasmodic pain in the left chest and the seizures have persisted. He has slept poorly, with harassing dreams; the appetite is poor, with continued emaciation, having lost about thirty pounds of flesh; the general appearance is progressively worse. The measurements of arm, shoulder and chest, a year after the accident, remain as they were on the first examination. Limited motion is possible, but with very little strength on resistance tests, and practically no grip.

He had been lefthanded and a baseball pitcher. An examination for life insurance a few days before the accident had shown a perfect physique. No neuropathic tendencies can be found in the family. The attacks of spasmodic pain and the seizures have been repeatedly observed by Dr. H. N. McDonald, a very close observer, from whom the case was referred in consultation, establishing their identity as typical attacks of true angina and epilepsy.

The literature of results of injury from powerful electrical currents is very meager and our knowledge of possible effects is very limited. Opinion at present confines them mainly to gross destruction of tissue, general func-

tional shock, or fatal outcome, but such conclusions, in view of our knowledge of the effects of galvanic currents on tissues and functions, are too narrow and our observations too limited. Much must depend on the voltage of the current, the duration of the shock, the possible presence of additional induced currents of very high voltage that may be present and that can not be definitely determined in the individual case.

This young man was in the circuit of a 500-volt current for probably about a minute. The current produced a general neuritis of the entire brachial plexus and the supply to the left chest, and the vagus is undoubtedly in the same condition, giving rise to the angina. In what way the shock or effect of the current has given rise to the epileptic element of the picture, whether by functional or organic injury to the nervous system, can not be determined. The distribution of the anesthesia, not being absolutely anatomical, may be assumed as hysteric in type, but the possibility that a powerful electric current diffusing from the point of contact over the surface may affect the cutaneous nerve endings over an extensive area without involving the entire anatomical distribution of the nerves involved, must be kept in mind.

This brief report is made only as a contribution to the literature of electrical injuries and their results, without reference to the control or outcome of the individual case.

#### TRAUMATIC NEURITIS AND PERSISTENT BRACHIAL NEURALGIA FROM HYPODERMIC INJECTION.

A large woman, of 52 years, of rheumatic and somewhat neurotic family history, had rheumatic fever several times between her 5th and 23d year. Two years ago she was under a physician's care for gastric ulcer and neuralgia, suffering very severe pain. The physician used morphia freely by hypodermic injection, selecting a very peculiar place to introduce the needle. All the injections were given in the wrists, making scores of punctures. On one occasion, instantly on the insertion of the needle, the patient felt a shooting, burning pain of great intensity run the entire length of the arm, which continued, and was quickly followed by swelling of the arm. This became extreme, with diffuse redness and heat, and great pain and tenderness. Dark red streaks extended up the arm from wrist to axilla. The swelling did not entirely subside for over two months. The pain was continuous, varying in intensity, but the suffering was intense.

She first came under observation about a month later. The arm at this time appeared normal in outline, except for moderate swelling over the tendons of the right wrist, and some loss of substance in the adductors of the thumb. Numbness was present in the little and third fingers. There was complaint of great pain extending up the arm from the wrist to the shoulder, along the course of the ulnar nerve more especially, but also along the median as well. There was decided tenderness along the flexor surface of the forearm. Movements of the arm or hand aggravated the pain, and they were kept as quiet as possible. The pain prevented sleep a great part of the time. Changes in the weather affected the condition profoundly.

She was put on large doses of salophen; lithia was also employed, and chlorotone as an hypnotic. Hot salt baths were directed for the arm, and an external application of equal parts of pure guaiacol and olive oil. The constant current was also used three times a week or daily, with long sittings, from forty minutes to an hour, with large electrodes, stable, from 10 to 15 milliamperes.

Short applications of the current produced little or no impression on the pain. The long sittings invariably diminished and finally relieved it entirely for increasingly longer periods following the sitting. The condition improved pretty steadily, but with occasional exacerbations, until after a little more than a year of treatment the pain had entirely disappeared. The adductors of the thumb were restored; she was sleeping well, and beginning to use the hand quite freely without exciting pain, and recovery was considered practically complete. When one day getting on a street car, it started just as she stepped on the lowest step, throwing her backward. She grasped the handrail to save herself, and, weighing 240 pounds, it gave her arm a severe strain. This caused a return of the intense pain, marked swelling of the entire arm, with a temperature of 100, pulse 90. The pain required heavy sedatives night and day, preventing sleep, accompanied by nausea, and causing marked exhaustion, which still obtain.

The use of the hypodermic needle as employed in this case is, of course, an extreme illustration, but it will serve to point to the fact that subcutaneous medication is used more freely and promiscuously than is at all necessary, and while when properly done the danger of any unpleasant result is remote, it is always a contingency and should be employed much less freely than it is.

This case and the preceding one suggest a thought in reference to the method of employment of the galvanic current. In the writer's experience, applied according to usual routine, for a few minutes, with small electrodes and weak currents, there is no perceptible result. Currents of fair strength, applied with large electrodes for a sufficient length of time to produce a sustained physiologic effect, must manifestly be necessary to produce any distinct therapeutic result.

The effect of changes of weather on many nervous states, and especially on painful conditions, as noted in this case, is very striking; it is not given sufficient attention, and often discomforts both patient and physician.

Another important point illustrated by the last case is the recommendation so often given by the general practitioner to patients suffering from painful conditions of the extremities, to use them all they can. Usually exactly the opposite thing should be done. In most such cases the extremity or part should be kept as quiet as possible and as free as may be from all effort and strain.

#### ALEXIA FROM CYST CAUSED BY BULLET WOUND—OPERATION—DEATH.\*

G. W. McCASKEY, M.D.

FORT WAYNE, INDIANA.

The following case is reported simply to illustrate the value of that form of aphasia known as alexia as a localizing symptom, and which led in this case to a successful surgical procedure.

Mrs. T., aged 31, was referred to me by a surgeon for diagnosis, with a view to operation if deemed advisable. Seven years before my examination she was shot in the head, by some unknown person, while riding in a buggy after dark. The bullet entered the skull  $4\frac{1}{2}$  inches to the left of the sagittal suture, and  $\frac{1}{2}$  inch in front of the binauricular line, proceeding in an unknown direction. She was in bed two months, and for four weeks was semi-conscious and delirious. After getting out of bed she was unable to walk alone for four

months. From this time on she was able to walk with a limp, the right leg being distinctly paretic. For several months after the injury she was unable to talk, and since then has had more or less speech disturbance constantly.

A few months before she came to the hospital she had an abscess in the right ear, which was preceded by severe occipital pain, relieved by the spontaneous discharge of pus. No other change had taken place in the patient's condition until within a few weeks, when the symptoms all began to grow worse, and continued to do so up to the time of my examination, at which time operative relief had been sought. There was severe headache, with marked increase of speech disturbance, and some increase of paretic weakness of right side. The history of the case, and the obviously downward tendency, pointed to an inevitably fatal termination in the near future, and appeared to justify the hazard of an attempt to relieve by surgical procedure if the localization could be made with sufficient accuracy. A careful study of the case elicited the following data: There was marked paretic weakness of the right hand and right arm. The patient could walk, but limped badly. The dynamometer registered eight in the right hand and twenty in the left. Right side of face was paretic. The right knee-jerk was grossly exaggerated, the left normal. The right elbow-jerk and jaw-jerk also exaggerated. There was no ankle clonus. Sensation was greatly impaired throughout the right side. On the right side of tongue she could not recognize two points of esthesiometer  $\frac{3}{4}$  inch apart. Over the right extremities and side of trunk she could not recognize two points of contact anywhere, at any distance.

Vision was normal in both eyes, and the visual fields unimpaired. Ophthalmoscopic examination showed a perfectly normal eyeground. The sense of smell was normal, but that of taste was slightly impaired. There was severe headache localized in upper and back part of head on left side. The mental condition was not very good. There was a certain degree of dulness, and considerable emotional instability.

The highest interest, however, attached to the speech disturbances. She could recognize the different letters of the alphabet, and would correctly spell any word shown to her; but could not recognize and pronounce, after spelling it, the simplest monosyllable. Such words as *was*, *in*, *horse*, *pencil*, *cat*, were perfectly meaningless collections of letters, no matter how often she spelt them over and studied them. If, on the other hand, I would vocally spell the word to her she would pronounce it at once, and easily apprehend its meaning. There was a certain degree of partial agraphia. Many words she could write correctly, while others she could not write at all. The individual letters could be made without difficulty, although the writing had to be done with the left hand, on account of the paretic weakness of the right. Her ability to combine the written letters into words, however, seemed to depend largely upon the simplicity of the latter. Her first name, for instance, was *Anne*. This she could always write without an error. Her family name, however, had four syllables, and it was impossible for her to write this at any time. I can not quote her efforts, as I do not wish to make identification possible for several reasons, one of which will be apparent in the sequel. The first syllable of the name was always written correctly, but the next letter was nearly always the last letter of the second syllable, while succeeding letters were entirely haphazard. She spelt Ohio, the state in which she lived, without the *i*. When her atten-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

tion was called to it she thought there was something wrong with the spelling, but could not tell what it was. She was unable to spell the simplest monosyllables which I would pronounce to her, although if I spelt the word she would correctly pronounce it.

The diagnosis of a destructive lesion of the angular gyrus was made. Pathologically it was thought to be either a cyst or an abscess, resulting from a chronic latent infection introduced with the bullet, with the probabilities in favor of the last named condition. The more diffuse lesion of the motor tract was believed to be the result of secondary inflammatory or degenerative processes, partial in character, though large in extent.

The diagnosis of a cortical lesion, and therefore one susceptible to exploratory procedure, and possibly open to operative relief, was made on the following grounds, both of exclusion and inclusion. The internal capsule was excluded as the seat of the lesion, because it was not believed possible that a traumatism could be produced here by a bullet, which would be so limited in final results as indicated by the symptoms in this case. It could scarcely be subcortical, for exactly the opposite reason; but aside from that there was another fact, which, taken independently, proved its cortical location, namely, the presence of alexia without hemianopsia. Had it been subcortical, and the alexia the result of injury to the fibers leading down from the cortex of the angular gyrus, the fibers passing forward from the cuneus, which lie immediately beneath it, would certainly have been destroyed, and homonymous hemianopsia would have resulted.

As the patient was going steadily downward, an operation was recommended with the hope of arresting the progress of the symptoms, and possibly palliating those already existing.

The surgeon, therefore, removed a small section of the cranial vault at the point which I indicated and immediately beneath it lay the bullet, with a small spiculum of bone attached to it, carried, of course, from the point of entrance. It lay embedded in the cortex, and adjoining it was a cyst of irregular shape and about  $1\frac{1}{4}$  inches in diameter, and which was evidently the cause of the progressive character of the symptoms. The bullet and spiculum of bone were removed, the cyst evacuated, and the operation completed without any event worth noting from a neurological point of view. There was some laceration of the cortex, which bled rather freely, but was apparently completely arrested before the operation was closed.

I saw the patient frequently during the day and evening at the surgeon's request, and about 9 p. m., some ten hours after the operation, I found the pupil on the side of the operation greatly dilated—the condition known as Hutchinson's pupil—and at once notified the surgeon that there was pressure from concealed hemorrhage, and that an exit should be provided by opening the dressing at once. At that time there was no coma or other evidence of increased general intracranial pressure. The patient's condition was extremely satisfactory, considering the circumstances. To my great regret the advice was unheeded, and during the night the patient passed into coma and died before morning. No autopsy could be secured.

The occurrence of alexia, as an isolated type of aphasia, and especially occurring as a sequel of traumatism, appeared to me to be probably of sufficient rarity to make it worth while to put the case on record. While the occurrence of Hutchinson's pupil under such cir-

cumstances is sufficiently well understood, yet the tragic lesson which it taught in this case ought at least to be long remembered by the surgeon in charge. There is every reason to believe that if the warning had been heeded the patient would have had an excellent chance for recovery from the operation, and considerable symptomatic relief.

## THE ECONOMIC LIMITATIONS OF THE VISUAL ACUITY IN VARIOUS TRADES AND PROFESSIONS.\*

H. V. WÜRDEMANN, M.D.

MILWAUKEE, WIS.

The central acuity lies within well-known physiologic limits. When it falls below this, the function itself is damaged, but the conditions met with in practice are not such that the physiologic and earning limitations of the central visual acuity are interdependent; for instance, science calls an individual blind only when perception of light has entirely disappeared, but in actual practice he is blind if the faculty of sight has been weakened to such an extent that the organ of vision can not be used to earn a living. Thus the meaning of blindness as used in daily life is much narrower than that of science.

Now and then extremely great demands may be made upon certain organs which may reach to the highest ability. In actual practice we are satisfied with the amount of labor which does not strain the powers. There is hardly any vocation which demands the extreme limit of sight (according to scientific figures) as a condition of success, and in each trade a great many individuals may be found who have comparatively poor sight but the same earning ability as those with normal eyes. Neither the lowest nor the highest points of scientific visual acuity correspond with those used in business; the lowest point of the latter is not as low as the lowest laid down by science, while the highest point of the functional range that may be regarded as normal must be considered below the highest scientific standard.

Certain estimations of the working acuity have been made from experience, and thus we have determined that ordinary coarse work, such as that of a farmer or day laborer, does not require more than one-half the normal acuity as a condition of success; for instance, if a day laborer should suddenly have his vision reduced to not more than 0.50 (one-half), he would be able to go on with his work; but, if a skilled mechanic would suddenly lose this amount of vision, he would have to stop, as he is used to work with clear retinal impressions; but if he would only lose one-quarter of his visual acuity he would yet be able to do all his work, as 75 per cent. would be sufficient for all ordinary demands. If the common laborer's vision should drop to less than 0.05, he would be blind for all working purposes, and the same might be said of the skilled artisan if his vision drop below 0.15. Therefore, out of these four limit values we have constructed two ranges within which the professional or economic limits lie. One of these ranges would have its highest limit 0.75 (three-quarters) as the lowest 0.15 (one-seventh); while the other range would be between 0.50 (one-half) and 0.05 (one-twentieth) of the normal scientific standard for visual acuity. It is not necessary that the maximum

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

and minimum limit values exist in both eyes. It is sufficient that they may be shown in one eye, the other having the lesser acuity than that which we have declared as absolutely necessary for professional visual demands. According to this standard tables are submitted which divide the followers of the different trades and professions into two groups.

Group 1—Trades requiring higher degrees of visual acuity; range 0.75 to 0.15.

## TRADES AND PROFESSIONS.

|                               |  |
|-------------------------------|--|
| The higher professions.       | The textile industry.                          |
| Medicine.                     | The silk industry.                             |
| Theology.                     | Paper workers.                                 |
| Law.                          | Leather workers.                               |
| Art.                          | Garment makers.                                |
| Engineering.                  | Printers.                                      |
| Students of all professions.  | Marine employes.                               |
| Fine mechanics.               | Mine workers.                                  |
| Iron and steel workers.       | Railway and steamship employes (including city |
| Rolling-mill workers.         | roads).  |
| Machinists and metal workers. | Soldiers and sailors.                          |
| Precious-metal workers.       | Telegraph operators.                           |
| Musical instrument makers.    | Skilled labor generally, etc.                  |
| The linen industry.           |  |

Group 2—Trades requiring lower degrees of visual acuity; range 0.50 to 0.05.

|                                   |   |
|-----------------------------------|---|
| Glass blowers.                    | Sugar factory employes.                 |
| Mine workers.                     | Brewers and maltsters.                  |
| Quarry men.                       | Tobacco workers.                        |
| Builders.                         | Chimney sweeps.                         |
| Pottery makers.                   | Street railway employes                 |
| Brick makers.                     | (horse cars).                           |
| Workers in mechanical industries. | Employes of elevators and wine cellars. |
| Employes in gas and water works.  | Teamsters.                              |
| Paper makers.                     | Bargemen on inland waters               |
| Wood workers.                     | (rivers, etc.)                          |
| Mill employes.                    | Farmers.                                |
| Manufacturers of food articles.   | Day laborers.                           |
|                                   | Unskilled labor, etc.                   |

Individual members of certain trades do not have exactly the same visual demands made upon them. This fact must be remembered and all the members of the same trade not judged by the same standard. Thus the railway employes may be properly divided into two classes.

It is advisable to reach some definite agreement as soon as possible, as hitherto there has been a disposition among oculists to consider the scientific results of the examination of the visual acuity as the basis for the valuation of the conditions arising in practical life. If the estimation of the results of the amount of damage arising from ocular injuries is to be made in a just manner according to actual conditions, this custom must be abandoned.

Our views regarding the difference between the scientific and working standards of visual acuity can claim far more extensive practical consideration than that which relates alone to the subject in hand of ocular injuries. All professions or vocations which make admission dependent upon a degree of vision would do well to remember that practical visual acuity and that of the scientific standard are entirely different things and that an individual may have, for working purposes, a full amount of vision who by the scientific standard shows a deficit. In the German army "a small disability which does not destroy the general fitness," i. e.,  $V. = 0.50$  allows of the recruit being received; a visual acuity in both eyes between one-half and one-fourth is called "conditional," and if one-fourth or below is called "absolute unfitness."

Magnus' suggestions have been accepted since 1893

in the Breslau Railroad Company. Their requirements do not now include normal acuity of vision by the scientific standard, but only "sufficient" visual acuity. The same conditions have been met with in a similar manner in other portions of Germany. In America the tendency is to demand the highest visual qualifications from prospective railway employes; the full scientific standard, 1.0 (20/XX), being required by many railroads and being deemed as essential by the consulting oculists of the principal systems.

Allport recently inquired into the conditions existent in the United States relative to the vision required by railway employes and comes to the conclusion that it is well to divide these employes into two classes: Class A, in which the vision should be at least 20/XXX (0.66) in one eye and 20/XL (0.50) in the other; Class B, in which the vision should be at least 20/XL (0.50) in one eye and 20/L (0.40) in the other. In the first class are to be put: Engineers, firemen, brakemen, conductors, switchmen, signalmen, switch-tenders and engine-dispatchers. In Class B: Track foremen, bridge foremen, crossing flagmen, bridge tenders, gatemen, train baggagemen, telegraph operators, station agents and station baggagemen. Other examiners require much higher qualifications. We are, however, fast coming to the conclusion that a practical working or economic vision should be required for new men, i. e., 0.75, and that they should not have any grade of refractive error which would ultimately render their distant vision poor without glasses.

The following table shows the scientific standard for the visual acuity converted into economic terms:

| I.                   |   |       | II.                  |   |     |
|----------------------|---|-------|----------------------|---|-----|
| Scientific standard. | Economic standard for vocations demanding higher degrees. |       | Scientific standard. | Economic standard for vocations demanding lesser degrees. |     |
| 0.75                 | 1   | 0.50  | 1                    |   |     |
| 0.70                 | 0.9166  | 11 12 | 0.45                 | 0.8888  | 8 9 |
| 0.65                 | 0.8333  | 10 12 | 0.40                 | 0.7777  | 7 9 |
| 0.60                 | 0.7500  | 9 12  | 0.35                 | 0.6999  | 6 9 |
| 0.55                 | 0.6666  | 8 12  | 0.30                 | 0.5555  | 5 9 |
| 0.50                 | 0.5833  | 7 12  | 0.25                 | 0.4444  | 4 9 |
| 0.45                 | 0.5000  | 6 12  | 0.20                 | 0.3333  | 3 9 |
| 0.40                 | 0.4166  | 5 12  | 0.15                 | 0.2222  | 2 9 |
| 0.35                 | 0.3333  | 4 12  | 0.10                 | 0.1111  | 1 9 |
| 0.30                 | 0.2500  | 3 12  | 0.05                 | 0.0000  |     |
| 0.25                 | 0.1666  | 2 12  |                      |   |     |
| 0.20                 | 0.0833  | 1 12  |                      |   |     |
| 0.15                 | 0.0000  |       |                      |   |     |

In calculating the amount of economic damage from ocular accidents the visual acuity should always be estimated from the economic standard. This may be readily done by the use of the above table, or by marking the economic values on our ordinary Snellen test cards. If we desire to estimate them ourselves, the economic valuation of certain visual acuities found by the scientific measurement, we may use the accompanying diagram, which offers an easy method for this transposition.

We show, figuratively, the relations between the scientific and the economic visual acuity in Plate I. In this drawing the degrees of vision in the absciss and the ordinate axis are marked at intervals of 0.01, so that five of these cards are always taken together, the absciss as well as the ordinate axis are divided by this into 20 equal parts. The curve of the scientific visual acuity is marked as a black line (1) and because this progresses gradually it has been equally divided. We are perhaps less exact in marking the deviations of the yellow and red lines or curves, which stand for the economic visual acuity, as we must admit that the working acuity is not diminished or enhanced in exactly the same manner as the scientific. Economic vision will not suffer very much if the acuity falls off 0.05, because the difference between 1 and 0.95 is so little that it will scarcely be noticed.

But, if the acuity fails off further, a point will soon be reached where every loss affects the working capacity, and if the vision falls below this point, for instance to 0.05, then it has no economic value whatever, and when it reaches this lowest point and further depreciates, vision will be professionally of no importance. Corresponding with these facts, the two curves of the economic visual acuity should not be marked as grades, the beginning and end of the curves should deviate, as we have shown; but these deviations are so little that we have divided them similarly to that of the scientific standard. The thin line (II) shows the course of economic vision for higher and the dotted (III) line for trades having lesser demands. As the drawing shows, both curves start together with the absciss-axis, and then when the climax of the demands is reached, they run parallel.

We also show on the ordinary Snellen test cards, both distant and near, the relations of business visual demands to the scientific standards.

The normal visual requirements of trades and professions should always be ascertained before examining applicants for admission, advancement or retention in service. If we adhere to the highest scientific requirements in certain trades many valuable men would be prevented from work and both the workman and the business injured thereby.

By requiring "normal" or "average" visual acuity we thus conserve both interests and yet sufficiently protect the public.

**Bilateral Ovariectomy During Pregnancy.** Löwenberg relates in the *Chil. f. Gyn.*, of December 21, the case of a patient in the third to fourth month of pregnancy who exhibited for several days symptoms indicating torsion of an ovarian tumor. The ovary had to be removed entirely on one side, and a large portion was resected from the other ovary, and yet the pregnancy continued undisturbed.

## WHAT AMOUNT OF VISUAL DEFECT SHOULD DISQUALIFY IN RAILROAD SERVICE?

FRANK ALLPORT, M.D.

Professor of Ophthalmology and Otolaryngology in Northwestern University Woman's Medical School, Professor Ophthalmology in Chicago Polyclinic, Oculist and Aurist to St. Luke's, St. Joseph's and Wesley Hospitals, Etc.  
CHICAGO.

(Continued from THE JOURNAL A. M. A., Oct. 13, 1901.)

At the last meeting of the Ophthalmological Section of the American Medical Association, I presented a report on the above subject, accompanied by tabulated statistics. In order to accumulate material for this report, I sent letters of inquiry and a question blank to every railroad in the United States, Canada and Mexico, operating over one hundred miles of road; 244 railroads were thus addressed, covering 205,638 miles of road. I received replies from 64 roads operating 90,950 miles of road. This left a large amount of mileage unaccounted for, and in order to endeavor to supply this deficiency, during the past year I communicated with all those roads failing to reply to my first communication. I received replies from 48 roads, making a total of 112 roads that have replied to my letters of inquiry. The roads thus heard from during the past year cover a mileage of 56,888 miles, making a total of 147,838 miles that are now accounted for. This leaves a deficiency of only 57,800 miles not covered in the combined report of the last two years; or, to put it differently, out of 244 roads to whom letters of inquiry have been sent, 132 have not seen fit to reply. These roads, I am glad to say, are mostly small roads, and the reports which I submit to you cover the requirements of most of the large railroad arteries of North America.

In itemizing the different points covered by my reports, I now beg leave to combine the replies received last year and those received this year.

I find, then, that out of 112 roads reported, 77 require some kind of a systematic eye and ear examination of those employees who are actively engaged in running trains, and in giving and receiving signals; 29 of these roads require such examinations to be made by regularly appointed railway surgeons; 31 allow various kinds of instructed railway employees to make the examinations; 9 roads send doubtful cases to an eye and ear surgeon; 16 roads require examinations to be made by regularly appointed eye and ear surgeons, and 4 allow such examinations to be made by the medical directors of Railway Relief Associations.

In answer to the question: "Do you require re-examinations from time to time, and if so, at what intervals or under what circumstances?" I find that 1 road requires re-examinations every six months, 7 roads require re-examinations every year, 21 roads every two years, 9 roads every three years, 2 roads every four years, 19 roads require re-examinations when it is deemed advisable, and especially upon promotion and after accidents and illnesses; 3 roads require re-examinations on promotion only.

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Wüldemann.

Concerning the question: "Do you require perfect vision, color sense and hearing in new employes? And what concessions do you permit from a perfect standard in the case of old employes?" I find that 26 roads require perfection, and allow no concessions to old employes, 41 roads require perfection from new applicants and allow various concessions to old employes according to circumstances.

Concerning the question: "How long must a man work for your road before you call him an old employe?" I find that 2 roads call a man an old employe as soon as he is enrolled in the service, 7 roads require one year's service, 3 roads two years, 12 roads three years, 12 roads five years, 7 roads ten years, 3 roads fifteen years.

Concerning the question: "Do you permit old employes to wear glasses for distance when on duty?" I find that no road allows new applicants to wear glasses for distance in order to bring vision up to a normal standard, 74 roads allow old employes to wear glasses for distance, 12 roads do not allow glasses to be worn for distance at all.

My views upon this important subject were fully expressed in the paper which I had the honor to present before this Section last year. I, therefore, have nothing further to say on the subject.

#### REPORT OF COMMITTEE.

Mr. Chairman and Members of the Ophthalmological Section of the American Medical Association:

Your Committee, appointed three years ago, with the view of framing resolutions for the regulation of the eye and ear requirements of transportation employes, were unable two years ago to bring in a unanimous report. The committee was, therefore, requested to retain its membership and endeavor to report at the following meeting. Meanwhile the committee was led to believe that action upon this subject would be taken one year ago by the International Medical Congress meeting in Paris. It was, therefore, deemed wise to wait until the committee of the International Congress submitted its report, feeling that valuable ideas might be therein contained, which would enable us to improve the character of our own work. The committee, therefore, did not report at the city of Columbus, and since then, although the chairman of this committee has endeavored with all possible assiduity to ascertain something concerning the nature of the work accomplished along these lines by the International Congress, he has been absolutely unable, up to the present time, although inquiry has been made along every possible avenue, to ascertain whether any work of this nature was accomplished or not. It, therefore, seemed useless to wait for the action of our European confrères, believing that it is not necessary for a country which leads all other countries in its transportation facilities to await the action of other nations. Your committee, therefore, begs leave to submit to the Section the following resolutions, which have been unanimously adopted and which is hoped will also be adopted by the American Medical Association, and then correctly placed before the proper railroad authorities of North America.

This work should be superintended by this Section.

SECTION 1. The essential principle to be advocated is that railroad corporations shall require a scientific and correct examination of the eyes and ears of those employes at all to be concerned with the active operating of trains, or in giving or receiving signals.

SEC. 2. Such *primary* examinations should, whenever possible, be made by regularly appointed eye and ear surgeons, and this point is emphatically urged, especially as the expense of a first examination may always be borne by the applicant; but if such a course is not deemed expedient, the company's surgeon, aided by his medical assistants, might conduct them, with the understanding that all doubtful cases shall be sent to a regularly appointed eye and ear surgeon.

SEC. 3. There shall be two general standards of visual and aural requirements, viz., those for new men hoping to enter the service, and to be actively engaged in the operation of trains, and in giving and receiving signals; and secondly, those men engaged in similar work, who have been uninterruptedly in a company's service for five years, and who have, therefore, a right to be called old employes.

SEC. 4. New men shall be required to possess perfect color sense. They shall also have a vision of 20/20 in each eye, without glasses, and have healthy eyes, and not over one diopter of hypermetropia. They shall also hear the whispered voice at 20 feet in a quiet room, and have healthy ears.

SEC. 5. For the purposes of graduated requirements old employes shall be divided into two classes as follows: Class A—Engineers, firemen, conductors, brakemen, switchmen, signal-men, switchtenders, and engine dispatchers. Class B—Track foremen, bridge foremen, crossing flagmen, bridge tenders, gatemen, train baggagemen, telegraph operators, station agents, and station baggagemen.

Employes enumerated in Class A shall not be retained in such positions if vision sinks below 20/30 in one eye and 20/40 in the other, or if the whispered voice can not be heard in a quiet room at 15 feet by one ear and 10 feet by the other. Employes enumerated in Class B shall not be retained in such positions if vision sinks below 20/40 in one eye and 20/50 in the other, or if the whispered voice can not be heard in a quiet room at 10 feet by both ears. Employes, and especially engineers and firemen enumerated in Class A, must reach the visual standard without glasses and will not be allowed to wear distance glasses when on duty. Employes enumerated in Class B may reach the visual standard with glasses, and will be allowed to wear glasses when on duty, and will be required to do so if the wearing of glasses is necessary to bring vision up to the proper standard, and shall always be required to carry an extra pair of glasses when on duty in case of accident to one pair. All employes shall have perfect color sense.

SEC. 6. Re-examinations shall be made of all men every three years, and after a severe illness, or accident, or any occurrence which seems to cast doubt on the visual and aural capacity of an individual. Re-examinations shall also be made more frequently on men known to be excessive users of tobacco, or to be suffering from syphilis, albuminuria, diabetes, or acute or chronic eye and ear diseases. Men shall always be re-examined before promotion.

SEC. 7. Men known to be excessive users of liquor shall not receive employment.

Respectfully submitted,

FRANK ALLPORT, M. D.,

Chairman of Committee.

92 State Street.

DISCUSSION ON PAPERS OF DRS. WUERDEMANN AND ALLPORT.

DR. LEWIS H. TAYLOR, Wilkesbarre, Pa.—This report has stated very clearly what we ought to have and should expect of railroad employes. It seems to me, however, that in many cases there is a lack of understanding and a lack of common sense in dealing with this matter on the part of railroad officials. I have in mind the case of a man who was dismissed from his place as engineer, a position he had filled for many years, who had excellent vision in one eye but was cross-eyed and had been for years. He wished me to operate and improve his vision if possible. I operated and got a good cosmetic effect, but, of course, could not improve his vision very much in the amblyopic eye, and he was not allowed to wear glasses. I have examined a number of others dismissed under somewhat similar circumstances, because the vision of the two eyes was not equal. It seems to me we should try to correct the false impressions that have given rise to the prejudices some railroad officials seem to have. I find that even men employed about the yards, in laboring work, are not allowed by some roads to wear glasses. I think it is a good work that the Committee is doing in educating the employes to a proper consideration of what is necessary, but we should also endeavor to educate their employers.

DR. H. B. YOUNG, Burlington, Iowa—There is an old saying to the effect that not everything that is true is expedient;

## ADDITIONAL STATISTICS ON "WHAT AMOUNT OF VISUAL

CONTINUED FROM JOURNAL OF AMERICAN MED.

| No. | Railroad.                            | Miles.          | Are eyes and ears systematically examined?                          | If so, what class of employees? And do you require same standard for all classes?  | Are such examinations made by an eye and ear surgeon, a general surgeon, or some railroad employe? | Do you require re-examinations from time to time, and if so, at what interval or under what circumstances?   |
|-----|--------------------------------------|-----------------|---|--|--|--|
|     |                                      | Forward, 90,950 |   |  |  |  |
| 65  | Kansas City, Fort Scott & Memphis    | 969             | Yes   | Train and enginemen  | By an eye and ear surgeon.   | New men and every three years thereafter.  |
| 66  | Burlington, Cedar Rapids & Northern. | 1,123           | Yes   | Employees in train service must have perfect vision. Station employees—vision can be corrected by the use of glasses when necessary.   | General surgeon and division surgeon.  | No.  |
| 67  | Rio Grande Southern                  | 180             | No.   | We require examinations only when we suspect defects.  | Local surgeon.   | No.  |
| 68  | Carolina & North-western             | 109             | No.   | We examine train employees, but not very exacting as compared with larger lines.   | By officer employing.  | Not unless have some reason for it.  |
| 69  | Boston & Albany                      | 389             | Eyes, yes; general hearing tested.                                  | All employees whose duties at any time may call upon them to observe signals.  | Railroad employes.   | Examination on employment; no re-examinations.   |
| 70  | San Francisco, San Joaquin Valley.   | 394             | Yes   | All engine, train and yardmen, crossing watchmen and signal towermen must be examined. Same standard for all.  | Eye and ear surgeon.   | Re-examinations every two years.   |
| 71  | Southern California.                 | 499             | Yes   | Same as above.   | Eye and ear surgeon.   | Re-examinations every two years.   |
| 72  | Chicago, St. Paul, Minn. & Omaha.    | 1,522           | Yes   | Engineers, firemen, conductors and brakemen.   | General surgeon.   | No.  |
| 73  | Texas Central.                       | 187             | Yes   | Our examinations extend to engineers, firemen, conductors, brakemen, machinists, carpenters, round house men, etc. No.   | Railway surgeon.   | No, unless the necessity calls for it on account of disease or injury.   |
| 74  | Mexican Southern                     | 278             | No  |  |  |  |
| 75  | Missouri, Kansas & Texas.            | 2,197           | Yes   | All employees in train service, including switchmen.   | Eye and ear and general surgeons.  | Re-examinations made at times of promotion.  |
| 76  | St. Louis South-western.             | 1,238           | Yes   | All employees in any branch of service where the use of signals or the movement of trains is involved are required to pass an examination on hearing, visual power and color perception. The same standard required from all classes of employees.   | By trainmaster, asst. supt., supt. and in a few remote cases by the local surgeon.                 | Re-examinations required from time to time; no set rule; limit of 3 years probable, except when called for on account of accident, illness or promotion. |
| 77  | Duluth, South Shore & Atlantic       | 586             | Yes   | Engineers and conductors.  | Traveling engineer & chief dispatcher.   | Every 3 years.   |
| 78  | Pacific Coast                        | 210             | Yes   | Engineers, firemen, conductors, brakemen, switchmen and flagmen.   | General surgeon.   | No; unless reason to think sight or hearing impaired.  |
| 79  | Seattle & International              | 166             | Yes   | Trainmen, engineers and firemen. Same standard.  | Eye and ear surgeon.   | Yearly.  |
| 80  | Evansville & Terre Haute.            | 167             | No  |  |  |  |
| 81  | Duluth & Iron Range                  | 161             | No record kept.   | We do not examine any employees in this respect regularly, or require such examinations.   | General surgeon, if at all.  | If we know of person having defect, exam. each year.   |
| 82  | Gulf & Ship Island                   | 143             | No  |  |  |  |
| 83  | Elgin, Joliet & East.                | 195             | No  |  |  |  |
| 84  | Chic. & N. W. & East.                | 366             | No  |  |  |  |
| 85  | Delaware & Hudson                    | 747             | Yes   | Engineers and firemen only.  | An employe.  | Not steadily; as indicated.  |
| 86  | Georgia                              | 307             | Yes   | All trainmen.  | Eye and ear surgeon.   | Two years.   |
| 87  | Central Ontario                      | 114             | No  |  | Not examined.  |  |
| 88  | Eric.                                | 1,188           | Yes; when employed.   | All those engaged in train service and who have to give and interpret signals. Same standard.  | Division officer; if defects are found, surgeon examines.  | Yes, if thought necessary in individual cases.   |
| 89  | Union Pacific                        | 2,985           | They are  | Employees are divided into two classes. Class A includes conductors, brakemen, engineers, firemen, signalmen, crossing flagmen, bridge tenders, switchmen, gatemen, train baggagemen, engine dispatchers, bridge and track foremen. Class B, agents, operators, baggagemen and other station employes. Standards for the two classes are not the same. See Question 6. | General surgeon; if defects are found the cases are referred to eye and ear surgeon.               | We do; all employees in train and station service were examined, beginning February, 1900. We expect to re-examine every 2 years.                        |
| 90  | Central, of Georgia.                 | 1,545           | No  | Those in operating department in fourth division at Columbus, Ga.; only applicants for position in operating department; first division at Savannah; those described in Class A, page 7.   | Company's surgeon at place of examination.   | Only when certain incidents bring into question the reliability of an employe.   |
| 91  | Virginia & South-western.            | 118             | Yes   | Enginemen and trainmen; same standard, both classes of service.  | Employees; report to superintendent.   | If we deem it necessary.   |
| 92  | Chi., Mil. & St. P.                  | 6,320           | Yes   | Train and enginemen; yes.  | Employe.   | No regular intervals.  |
| 93  | Boston & Maine                       | 1,767           | Yes   | All men in train service having to do with signals.  | Employe; doubtful cases by specialist.   | As often as once in 2 years.   |
| 94  | Kansas City, Memphis & Birm.         | 282             | Yes   | All actual employees in train service are required to pass the same examination.   | Eye and ear surgeon.   | Yes, every 3 years.  |
| 95  |                                      |                 |   |  | Specialist, when made.   | No.  |
| 96  | Pere Marquette.                      | 1,884           |   | This road is now in process of organization; I am preparing a system of examination for all.   | Employees; not yet in operation.   |  |
| 97  | Burlington                           | 7,357           | Yes   | All employees handling signals in the moving of trains.  | Medical examiners of relief department.  | In all cases every 3 years; defective cases every year.  |
| 98  | Delaware, Lackawanna & Western.      | 900             | Yes   | Employees in any way connected with train, engine and yard service or with maintenance and operation of fixed signals, crossing flagmen, bridge and tunnel watchmen, etc; same standard.   | Company's oculist.   | Yes; 1 to 3 years, according to age.   |
| 99  | Interoceanic, of Mexico.             | 555             | Eyesight only.  | Engineers only.  | Railway employe.   | No rule.   |
| 100 | Chattanooga, Rome & Southern.        | 156             | No  | We have no regular requirements. If we find that the sight or hearing of an employe in train service is defective we have examined.  | We have some of our railroad surgeons examine.   | We only have examinations made when there is reason to suspect defects.  |
| 101 | Mexican National                     | 1,218           | No; men in train and yard service examined by train dept. officers. |  |  |  |
| 102 | Central, of New Jersey.              | 685             | Yes, new men; old men when they show weakness.                      | Enginemen, firemen, conductors, brakemen, operators, etc.; yes.  | Regular examiner, assisted by trainmaster.   | No; we accept as stated in No. 2. (Are eyes and ears systematically examined?)   |
| 103 | New York Central & Hudson River.     | 2,881           | Yes, certain employees.   | Enginemen, firemen and conductors.   | Superintendents.   | From time to time; depending on prev. exam. and age.   |
| 104 | Canada Atlantic                      | 178             | They are not  |  | Professional when necessary.   | No regular re-examinations.  |

## DEFECT SHOULD DISQUALIFY IN RAILROAD SERVICE."

CAL ASSOCIATION, VOL. XXXV., NO. 15, PAGE 920.

| Do you require perfect vision, color sense and hearing in new employees? And what concessions do you permit from a perfect standard in the case of old employees?   | How long must a man work for your road before you call him an old employee?  | Do you permit old employees to wear glasses when on duty?                          |
|---|--|--|
| Perfect vision, color sense and hearing for new men; and perfect vision and color sense and one-quarter or better in each ear.<br>Yes. No concessions.  | About one year . . . . .<br>No rule . . . . .  | Yes.<br>Yes, in certain lines of work.   |
| Yes. It has not been necessary up to this time to make any concessions. No. Only to that extent necessary to distinguish by sight and hearing signals under practical conditions.<br>Perfect vision and color sense required in new employees. Old employees judged according to the requirements of the position they occupy.<br>(1) Yes. (2) Certain concessions are made in case of old employees wherein no risk is involved.   | Three to 5 years . . . . .<br>One year . . . . .<br>No rule . . . . .  | No.<br>Old men.<br>Enginemen, no; trainmen, in some instances.<br>Yes.             |
| (1) Yes. (2) Certain concessions are made in the case of old employees, wherein no risk is involved.<br>New employees—yes. Old employees—cases passed upon individually, consideration being given to previous record, ability, etc.<br>As nearly perfect as possible in new employees 20/20. In old employees 20/30 or 20/40.  | No rule . . . . .<br>We consider men in employ previous to use of present rules old employees about five years . . . . .   | Yes.<br>In individual cases as above.<br>Yes.                                      |
| See circular hereto attached.   | No rule . . . . .<br>We have no rule covering this.  | No.<br>See circular.   |
| Perfect vision, color sense and hearing is required in all new employees. In the case of employees who have been in the service a year or more, or were in our employ at the time the system of examination was made effective, we have accepted 20/30 in one eye and 20/40 in the other, without glasses, but in the case of any defect in color sense or serious defect in hearing, relieve the employee.<br>Perfect for new employees. 5/20 from perfect standard in old employees.  | One year . . . . .<br>Three years . . . . .  | Yes.<br>Yes.   |
| New employees must be perfect. Old employees may wear glasses.  | Three years . . . . .  | Yes.   |
| Yes. Such as may be due to age, but distant vision must be normal.  | Not stated . . . . .<br>No rule . . . . .  | Yes.<br>None of them do.   |
| Have no special requirements in this regard.  | About 10 years . . . . .   | No rule, but few do wear glasses.  |
| In all employees.   | No rule . . . . .<br>Two years . . . . .<br>Two years . . . . .<br>No rule . . . . .<br>Adopted the plan 3 years ago . . . . .<br>Ten years . . . . .<br>No rule—probably 15 or 20 years . . . . . | Yes.<br>Yes.<br>Yes.<br>Yes.<br>Yes.<br>No.<br>Yes.                                |
| Some concessions in case of old employees<br>Yes. Must have perfect vision if it can be had with glasses.<br>Yes.<br>Yes. Old employees permitted to wear glasses if vision can be made normal thereby.   | No stated length of time. All employees examined at our biennial examinations will be considered "old employees." and the defective men disposed of as above stated.                               | We do.   |
| Vision requirements for Class A.—Normal in one eye and one-half normal in the other. Class B.—Two-thirds normal in one eye and not less than 20/70 in the other, without glasses. Hearing for both classes, normal in one ear and three-quarters normal in the other. Normal color sense required in both classes. Applicants for promotion in Class A must be re-examined. Concessions permitted from a perfect standard in the case of old employees are determined by a Board consisting of General Manager, Supt. transportation, Supt. Machinery, Supt. Telegraph and Chief Surgeon, who pass upon each individual case and take such action as is deemed advisable. In cases where the defect is serious and can not be corrected by the aid of glasses or surgical appliances, the employee is either relieved from service or transferred to another occupation or to branch line service, where his defect will not jeopardize the interests of the company. This class of employees are required to undergo re-examination every three or six months, nature of the case determining frequency of the examination. This is left to the discretion of the examining surgeon. | No ruling on this point.   | I have been told that the officials do allow this.                                 |
| Perfect new employees. Provided vision can be made satisfactory by glasses, permission is given for their use.<br>Yes. In case of old employee glasses must bring his sight to normal.  | Five years . . . . .<br>At least 15 years; have no fixed rule.   | Yes.<br>Yes, except engineers.   |
| 1. Yes. 2. Depends on nature of service.  | No rule . . . . .  |  |
| Vision new employees perfect. Old employees 20/20 (may use glasses). Hearing, new employees, 24/48; old employees, 12/48.<br>No. Examined as to 1, 2 and 3 (vision, color sense, hearing), unless for special reasons.  | Six months . . . . .<br>Three or years . . . . .   | Yes.<br>Yes.   |
| In engine service, normal color sense, hearing and normal vision in each eye. Train yard, etc., normal color sense, normal hearing, at least normal vision in one eye and not less than one-half normal in the other eye. For men in service each case handled as an individual case.<br>Yes. Old employees with defective vision only permitted to wear glasses fitted by Company's oculist.   | Can not say . . . . .  | Yes, for reading train orders only in engine and train service.                    |
| We require correct distinction of figures and colors at given distances.  | No rule . . . . .  | No rule.   |
| See answer to No. 5. (Do you require re-examination from time to time and if so, at what intervals or under what circumstances?)  | We have no fixed period.   | Yes, we would do so, though I believe we have only a few office men using glasses. |
| No.   | Three years or more . . . . .  | Yes.   |
| Yes. Normal   | Ninety days . . . . .  | Yes.   |
| See book of instructions.   | Opinions differ as to when a man should be called an "old" employee.   | Enginemen or firemen, not permitted to wear glasses; conductors, yes.              |
| Have not arranged for examination. Expect to do so at an early date.  | Have no age limit . . . . .  | No.  |

| No.            | Railroad.                                    | Miles.  | Are eyes and ears systematically examined? | If so, what class of employees? And do you require same standard for all classes?   | Are such examinations made by an eye and ear surgeon, a general surgeon, or some rail'd employee? | Do you require re-examinations from time to time, and if so, at what interval and under what circumstances? |
|----------------|--|---------|--|---|---|---|
| 105            | St. Louis and San Francisco.                 | 1,990   | No   | Vision test is made of employees in train service if any doubt of their vision being defective.                           | Competent oculist   | No.   |
| 106            | Houston E. & W. Texas, Houston & Shreveport. | 229     | Yes  | All trainmen, engineers, firemen, conductors brakemen.  | Surgeon at hospital.  | Expect to examine once every 12 to 16 months.   |
| 107            | Rio Grande West ern                          | 599     | Yes  | Only trainmen and engineers; same standard required   | Surgeon or oculist  | Started last May, and they have not been re-examined  |
| 108            | Ohio River                                   | 396     | Yes  | Engineers, firemen, brakemen, conductors, yardmen, switchmen; same standard.  | Chief surgeon; eye and ear surgeon  | Annually; examine all employees on entering service   |
| 109            | Washington County.                           | 137     | Yes  | Conductors, baggage masters (train), brakemen, firemen, engineers, yardmen, flagmen and signalmen; same standard for all. | Regularly appointed eye and ear surgeon.  | Every 3 years; after a severe illness or accident which may affect sight or hearing                         |
| 110            | Southern                                     | 6,415   | Yes  | Engineers, firemen, conductors, flagmen, brakemen, yardmen and hostlers.  | Designated officer of the company.  | Every 2 years, or oftener if it becomes necessary   |
| 111            | Pennsylvania.                                | 4,130   | Yes  | All who must govern their actions by our signals; the same standard for all.  | Division superint. thro' employees  | No regular intervals; before promotion and after accidents or serious illness.                              |
| 112            | Texas Midland.                               | 125     | No   | No examinations are made  | None made   | We do not   |
| Total mileage. |  | 147,838 |  |   |   |   |

and on this ground I am opposed to the adoption of our Committee's report. I think that for the present we should consider less the purely scientific aspect of the question and look at it more from the practical standpoint. When we come to do this we will get more cooperation from the railroad officials. We have got to take into consideration two things, and the first is that the employee upon whom the brunt of this burden will fall is the engineer. Now, on most of the railroads the engineer is an old employee; has been in service at least ten or perhaps twenty years (before vision tests were thought of); may have a record for efficient service without accidents; and yet as compared with the standards set up in this report his vision may be faulty. In other words, the service records of the men with 20 40 or perhaps 20 50 may compare favorably with those having 20 20 vision. The second is that investigations of accidents have not shown that faulty vision was the essential factor save in a few instances. I believe that the railroad officials are interested in this question more than we have given them credit for; and in the support of this I will say that, with the approval of the Assistant Superintendent of Motive Power (now superintendent) of the C., B. & Q., I have made some practical observations on the visual requirements of trainmen. In the past six months I have ridden some hundreds of miles on the front end of the train; and I have tried to get all sorts and conditions of atmosphere for these tests. I have found that on a stormy day, on a train like the Burlington No. 1, averaging about fifty miles an hour and running against the rain, it is impossible to keep the head outside of the cab and you can not see through the window. The engineer just dodges his head out and quickly back. Acuteness of vision (for one can not see much) is thus not so essential as quickness of perception; and this faculty lies not wholly in the eyes, as we know, but is largely a mental quality. I have found that when I reduce my vision to 20 40 there are no ordinary signals which an engineer can not see within stopping distances of these trains. There is in this test, however, a peculiar difference between day and night signals. One sees the night signals relatively better than the day signals. This is due to the fact that when one has 20 20 vision or better, the emergent rays of the signal lamps produce some dazzling effects; and these may lead to confusion where the lights are numerous. With 20 40 vision these rays are not perceived. The lights are seen as bright discs.

I have found also that by wearing glasses I could keep my head out of the cab in stormy weather when the engineer, without them, could not. It does not therefore seem such a bad thing for an engineer to wear glasses. But if an engineer can wear glasses for one thing, why not for another? Neither the engineers nor the public will discriminate between causes for wearing them. To allow one trainman to do a thing which another in the same service may not, because the one has been on duty twenty years and the other only ten, does not make easy sailing with the trainmen. To have two different standards of vision for these two classes will not, in the event of

an accident while the low standard man is in charge, make easy sailing with the public. If we want the cooperation of the railroad officials in our movement to farther safeguard the transportation of person and property, we must formulate rules more universally applicable.

DR. C. H. WILLIAMS, Boston—I wish to ask Dr. Allport if he wishes the Association to take final action on the report of the Committee as it stands.

DR. ALLPORT—If the Section sees fit to endorse the report as it stands we should like to have it brought before the Association as a whole for adoption, but the latter part can not be carried out at this year's meeting.

DR. WILLIAMS—I wanted to make that point clear before going on because it seems to me the report is not yet quite definite enough for us to recommend it to the Association. It seems to me that in order to get practical railroad men to listen to our recommendations we must do two things; we must separate, as has been recommended both by Dr. Wuerdemann and Dr. Allport, the requirement for men coming into the service from those required of old employees. We all agree upon the question of men coming into the service, but the difficulties come in dealing with the old employees and that difficulty is greater to-day than it will be a few years hence because by insisting upon a high standard for men coming into the service we will not have so many of these troublesome questions arising later on. Now, I am inclined to go a great deal further than the report of this Committee in what may be considered as the minimum limit of safety in old employees. Two and a half years ago I drew up for the New York, New Haven & Hartford Railroad some standards for the examination and re-examination of their men; these were put into operation for eighteen months on half of their system, then modified somewhat and extended to the whole system. These standards require that old employees be re-examined every three years and before promotion. The whispered voice is a most uncertain test for hearing and if you exclude the man who can not hear a voice at more than 15 feet I think it will not be entirely fair. I think you want both the voice test and one other, either the watch, or what I prefer, the ratchet acrometer. Another great difficulty with the report as presented is that it does not give in detail the method to be followed in making the examinations. For instance, in regard to color tests, I have had four men who passed the test with the Holmgren worsteds and the Thomson stick and yet when they looked at the lantern they mixed up the reds and greens in more than half the number of exposures! We must have something in addition to the worsted tests.

DR. H. V. WUERDEMANN, Milwaukee—I understand the Committee advises that all new men should have practically normal vision, that is, 20 20. Now, how many prospective railroad men have that amount? We threw down about 5 per cent. on account of color blindness, but is there not a much larger percentage who have more or less defective vision and who would yet be safe men to perform all the work required of a railroad employee? The question with the railroads is not

| Do you require perfect vision, color sense and hearing in new employees? And what concessions do you permit from a perfect standard in the case of old employees?   | How long must a man work for your road before you call him an old employee? | Do you permit old employees to wear glasses when on duty?                              |
|---|---|--|
| Not at this time. We are preparing a set of blanks for physical as well as eye and ear examination. All employees rated same; accept judgment of surgeon as to latitude of requirements.  | Do not classify them . . . . .  | Yes.   |
| Require not less than 20/30 in either eye, and not less than 20/25 in both eyes.  | No fixed period here; when the road was a narrow gauge.                     | No.  |
| New employees, 20/20 each eye; old employees, 20/20 one eye and 20/30 other eye.  | Over 6 years . . . . .  | Engineers, no; conductors, for reading. Distant vision must be good. Not on main line. |
| Perfect vision, color sense and hearing in new employees. Old employees granted a few concessions consistent with safety.   | When promoted from fireman to engineer or brakeman to conductor. . . . .    | No.  |
| Do not require perfect vision, color sense or hearing, but they must not be below the standard; old employees are allowed to wear glasses to correct defects in vision, eyes to be examined and glasses fitted by a designated oculist. | Five years . . . . .  | Yes, under conditions above mentioned.   |
| New employees, yes; old employees as per pamphlet. . . . .  | There is no class of "old employees."                                       | Yes.   |
| We do not . . . . .   | One year . . . . .  | Yes.   |

altogether what they should have but what they can get. I understand that in the West where there are many men seeking employment the railroads have considerable difficulty to get good men. I think the plan suggested by Dr. Williams is better, and would be adopted by the railroads quicker. As to whether we should demand good working vision in both eyes, I should say yes, by all means. A man with monocular vision is quite as good for most trades, but suppose an engineer with one bad eye gets a cinder in his good one. He is thrown out of place at once. Suppose such an accident should happen to both engineer and fireman at one time (and this is possible if not probable) it might bring about a serious predicament. As to the wearing of glasses on the train I think that only protective glasses should be used.

DR. WILLIAMS—Dr. Wuerdemann may not have understood me. In my experience there is no difficulty in securing new men for the railroad service in the East with 20/20 vision without glasses. I was speaking only of old employees.

DR. FRANK R. ALPORT, Chicago—This discussion, with its variety of individual opinions, exemplifies some of the difficulties under which your Committee has labored. The various members of the Committee live in different portions of the country, and it has been impossible, of course, to get them together. Those of the Committee who are at this meeting, met yesterday. For about a year, by means of frequent and numerous correspondence between the different members of the Committee, and by concessions and alterations on the part of all, we have finally unanimously agreed on this report as presented to you and feel that it is as good a one as can be produced at the present time. We realize its imperfections, and that alterations in its views will necessarily be made from time to time. But as this matter has been now held in abeyance for about three years, we feel that action should now be taken and the matter be placed in a position where it can progress. The Committee desires free discussion upon the subject, and is perfectly willing that alterations should be made in accordance with the desires of the Section, or if the Section feels that another Committee can do better work, I am sure we would all be glad to be relieved from the task. I do not agree with Dr. Wuerdemann in regard to the lack of railroad employees possessing perfect physical qualifications. I am told by railroad officials that there is plenty of good material, and I therefore feel that when a man for the first time presents himself to the railroad for work of a responsible character, that the road has a perfect right to demand practically perfect physical development. We have made provision for modifying these requirements as men grow old in the service of the road, but we earnestly recommend practically perfect eyes and ears when men first enter service, when the railroad is under no obligations to them. Some one has suggested that employees be allowed to wear glasses, and speaks of protecting glasses particularly. I presume no railroad would object to the wearing of mica glasses for protection, but after a careful consideration

of the problem, your Committee believes that men engaged on a locomotive engine, and carrying precious lives and valuable property behind them, should not be allowed to wear glasses for the improvement of distant vision. Dr. Williams, at the Atlantic City meeting, presented some regulations he had prepared for the New York, New Haven & Hartford Railroad and again makes reference to them at this meeting. He says that they test vision with both eyes open with no reference to the individual vision of each separate eye. This certainly seems a dangerous rule, for as I argued at Atlantic City, a man might be totally blind in one eye, under which circumstances it hardly seems that he should be allowed to retain as responsible a position as the running of a train. The Doctor also objects to the whispered voice as a test for hearing, and recommends an instrument which he has devised for this purpose. I believe the consensus of professional opinion is less and less in favor of the watch for the testing of hearing. In the German clinics such mechanisms have been almost entirely abandoned and the voice substituted, which appears to be the safest and most direct test we can adopt. Some member has objected to the question of finance being mentioned at all in these resolutions. The only reference to the matter is in one section where it is stated that the expense of a primary examination should be borne by the applicant. This certainly seems just, for at this stage of a man's career the road is under no obligations to him. If he desires to enter the service, there is no reason why he should not stand the expense of a clean bill of health, and it was felt that if the railroads were not burdened by a preliminary eye and ear examination by an eye and ear surgeon, that they would be more ready to comply with these suggestions.

Upon motion of Dr. Jackson, seconded by Dr. Risley, the report of the Committee was adopted, and the Committee discharged. The new Chairman of the Section was instructed to appoint a Committee to present the matter before the general session of the American Medical Association at its next meeting.

**Public Prophylaxis of Venereal Diseases.**—F. P. Guiard publishes an article in the December *Annales de Dermatologie et de Syph.*, which proclaims that a great advance would be made in the prevention of venereal diseases if prostitutes could be made to realize the possibility of protecting themselves against contagion by appropriate local antiseptic measures applied no later than five minutes. They should be thoroughly instructed in the dangers that threaten them from venereal diseases and also in the simple technique of prophylactic antiseptics. After extensive study of the best measures for the purpose, he recommends a 1 per 5000 solution of sublimate, from a fountain syringe, retained intermittently in the vagina by compression of the labia. All the recesses in the external genitalia should be rubbed with the same solution. This protects against syphilis and soft chancre as well as gonorrhea.

## THE PROBLEM OF HEREDITY.

JAMES G. KIERNAN, M.D.

Fellow of the Chicago Academy of Medicine, Foreign Associate  
Member French Medico-Psychologic Association.  
CHICAGO.

The individual who comes into the world is, as Luys<sup>1</sup> remarks, not an isolated being separated from his kindred. He is one link in a long chain which is unrolled by time, and of which the first links are lost in the past. He is bound to those who follow him and to the atavistic influence which he possesses; he serves for their temporary resting place, and he transmits them to his descendants. If he come from a race well endowed and well formed, he possesses the characteristics of organization which his ancestors have given him. He is ready for the combat of life and to pursue his way by his own virtues and energies. But inversely, if he spring from a stock which is already marked with an hereditary blemish and in which the development of the nervous system is incomplete, he comes into existence with a badly balanced organization, and his natural defects existing as germs and in a measure latent are ready to be developed when some accidental cause arises to start them into activity.

As Moreau (de Tours)<sup>2</sup> nearly half a century ago pointed out, an incorrect conception of heredity looks for identical phenomena in each succeeding generation. This view arises from the biologically unjustifiable belief, entirely too prevalent, that the human being is simply a product of two individuals and this product is perfectly formed from the start. To this view is due alike the credulity of those who claim absolute direct heredity of acquirements and the skepticism of those who absolutely deny these. In addition to immediate heredity three forces have to be recognized: immediate atavism, remote atavism and finally fetal environment and postnatal environment during growth. The embryo as a whole advances through a regulated system of atrophies and hypertrophies. If the immediate ancestry be weak or the maternal environment during fetal life be poor, the atavistic tendency of the remote type will gain at the expense of physiologic advance unless parried by the favorable influence of immediate atavism.

In essence no distinction can be drawn between pathologic or physiologic results in heredity. The only distinction is as to whether the hereditary acquirement, whether pathologic or physiologic, be anomalous or usual, in the species, race or family.

Transformation, metaplasia, change from one species into another, whether in man, animals or plants, or tissues, can not, as Virchow<sup>3</sup> remarked seven years ago, take place without anomaly; for if no anomaly appear this new departure is impossible. The physiologic norm hitherto subsisting is changed, and this change can not well be called anything but an anomaly. In former days an anomaly was called pathos and in this sense every departure from the norm is a pathologic event. If such pathologic event be ascertained; this forces investigation as to what pathos was the special cause of it. This cause may be, for example, an external force or a chemical substance or a physical agent producing in the normal condition of the body a change, an anomaly (pathos). This can become hereditary under some circumstances and then may be a foundation for slight hereditary characteristics propagated in a family. In themselves these belong to pathology, even though they produce no injury. Pathologic does not mean harmful, nor does it indicate disease. Disease in Greek is *nosos* and it is nosology that is concerned with disease. The

pathologic under some circumstances may be of advantage to its inheritor.

Whether certain defects shall prove malign or benign to the organism is determined by environment, whether intra-uterine, during the nursing period, or later. All vertebrate embryos at their origin are the same. They pass through many common types before being differentiated. Supernumerary organs exist in these common types at one phase of embryonic life. For these reasons repetition of teratologic types occurs in vertebrates. The higher vertebrate embryo contains in essence the organs and potentialities of all lower vertebrates. Under the influence of heredity or accidental defect, an organ, structure or function constant in a species may be lacking or excessive in an individual without remote atavism being involved. Varying conditions stimulate these embryonic potentialities at the expense of the later acquired and more typical human organs. Thus results a struggle for existence between organs and structures, early observed by Aristotle, Goethe and St. Hilaire, but fully demonstrated by Roux<sup>4</sup> two decades ago. He, while admitting determination by heredity, shows that surrounding forces are necessary, not simply the condition of activity by an essential element of the final product.

The introduction of variations depends on the fact of reproduction. It is usually assumed that sex differentiation is a *sine qua non* for reproduction. Sex differentiation does not exist in many of the higher invertebrates and parthenogenesis or virgin generation occurs in abortive form even among the vertebrates.<sup>5</sup> Even in mammals, not excepting man, the unimpregnated ovum is capable of imperfect development. The function of the male in heredity is, therefore, overestimated. The male among many invertebrates merely so adds nutriment to the developing ovum as to enable the embryo to pass through higher development than would otherwise be possible. As Jacques Loeb has shown, normal salt solutions may here be substituted for male fluids.<sup>6</sup> In certain invertebrates osmosis of similar fluids from the male occurs. The female function in reproduction is, hence, the most potent. The potency of the female in this particular increases with rise in the scale of life. Among viviparous mammals the product of conception remains under uterine control for a lengthy period and is nourished by the mother long after birth. Upon the mother, therefore, depends to a large extent the preservation of the race type and of any accidental variations introduced by the male.

In a general way there is an antagonism between the individual so far as personal existence is concerned and between the tendency to reproduction. It is from this antagonism that Weismann<sup>7</sup> has drawn the biologic difference between the body plasma which constitutes the individual and the germ plasma which reproduces the race. There are, hence, in every being two factors which vary in inverse ratio: The impulse of every individual to self-preservation and the impulse to the production of other individuals. The former diminishes when the latter augments. These two forces are necessarily antagonistic. In evolution of the compound organism, cells and structures have surrendered reproductive powers for the benefit of the whole organism. Local degenerations have, hence, occurred for general benefit.<sup>8</sup> Since certain parts in the evolution of organs disappear, and in the evolution of organisms certain organs through suppressive economy,<sup>9</sup> and since the disappearing and developing tendency of necessity centers around the time when certain functions are to be lost by the disappearing, and others

gained by the developing, periods of stress occur around which the law of economy of growth centers the struggle for existence between parts of organs and between organs themselves. It is because of this that physiologic atrophies and hypertrophies occur. Since the ovum when impregnated does not enter into a full course of development at once, and since the power of the embryo to pass through the different stages depends, as even Weismann admits, on its nutrition, the power of the embryo to pass through these different stages of stress will turn in part on its initial velocity from both parents. Heredity is shown in more or less complete development rather than in any specific quality.

Immediate atavism may be malign or benign as circumstances determine. In any event it tends to secure the race type as opposed to variation, whether in the direction of advance or degeneracy. Indeed, it may secure by certain degeneracies advance as opposed to remote atavism. If, at certain periods of intra-uterine stress through deficient nutrition, remote atavism gains the day, cerebral states result analogous to those of animals so far as the encephalic basis is concerned. The neuron passes successively through stages corresponding to those which are to be found in the adult fish, frog, bird and mammal. In this case development consists in an increasing complexity of the cell with no formation of unnecessary rudimentary parts. Its ontogeny in man usually repeats in modified form the main ancestral stages. This is peculiarly evident when the cerebral development of man is compared with that of the vertebrate series.

In fish and batrachia (ichthyopsidæ) the cerebral hemispheres do not cover the region of the third ventricle from which the eyes arise (thalamencephalon); in the human embryo of the seventh week, same. In reptiles and birds (sauropsidæ) the hemispheres cover the thalamencephalon, but leave uncovered the region of the optic lobes (mesencephalon); in the human embryo of the middle of the third month, same. In mammals the hemispheres cover the thalamencephalon (cerebellum and medulla) and the olfactory lobes; in the human embryo of the fifth month, same. In some mammals even of higher orders (*e. g.*, some hapalidæ) the hemispheres are smooth; in the human embryo of the middle of the fifth month, same.

Arrested development of the neurons would imply imperfect power of association and consequently imperfect potentialities for education. As the power of passing through the fetal period of stress depends on the condition in which the fetal organism is at the time of the period of stress, and as this condition of the fetal organism depends partly on factors inherited and partly on the maternal condition, defect in either at these periods of stress may so disarrange the struggle for existence between the fetal organs that reversionary conditions succeed.

Through degeneracy of certain inferior organs superior organs may draw to themselves under the law of economy of growth sufficient nutriment to obtain the ascendancy. The inferior organs may subsequently regain their power while the gain made by the superior organs is retained.<sup>10</sup>

Because of this struggle for existence between the different factors of heredity and because of a varying environment at the periods of stress, whether intra- or extra-uterine, hereditary acquisitions are rarely able to overcome remote or immediate atavism so as to pass through the periods of stress. Weismann's criticism,

therefore, while valid against absolutely direct heredity, does not hold against conditions affecting the organism as a whole. As Virchow has already pointed out demarcation between physiologic, abnormal and pathologic is a varying matter of degree, not kind. The opposite view vitiates the current conceptions of heredity of acquired characteristics. Stress has been laid on the distinction between the normal and abnormal as a reason for the non-inheritance of defect. Certain strongly opposed observations Weismann attempted to explain away by an exceedingly crude baseless theory. According to him, inherited epilepsy is due not to cerebral malformation, disorder or disease, but to infection by microbes. As the ovum can carry more microbes than the spermatozoon, epilepsy more frequently comes from the mother than the father. The grossly absurd baselessness of this theory needs no demonstration. It fails completely to explain the facts and to exclude every other explanation. Predisposition, according to Weismann, may occur in the children of the tuberculous; this is due not to inherited weakness but to some mysterious non-specific action.

Weismann claimed absolute distinction between the germ plasm and the body of plasm. This claim, which never explained reproduction by budding or reproduction of lost limbs in salamanders,<sup>7</sup> has been completely destroyed by late observations at the Naples Aquarium. These have emphatically demonstrated that no absolute distinction so far as reproduction is concerned exists between germ plasm and body plasm. The distinction between the germ plasm and body plasm theory of Weismann<sup>11</sup> and the pangenesis theory of Darwin is therefore of degree and not kind. Conditions occur in which cells regain the function of reproduction surrendered for the benefit of an organ or an organism. Weismann practically destroys the absoluteness of his claim by admitting that more or less considerable abnormalities may affect the course of development and either cause the death of the embryo or produce more or less marked deformities.<sup>12</sup>

From the interaction of remote atavism, immediate atavism, immediate heredity and maternal environment during pregnancy results transformation of heredity. An incorrect conception of heredity—as Moreau (de Tours) remarked nearly a half a century ago—"looks for identical phenomena in each succeeding generation. Some have refused to admit that mental faculties were subject to heredity because the mental characters of the descendants were not precisely those of the progenitors. Each generation must copy the preceding. Father and son must present the spectacle of one being, having two births, and each time leading the same life, under the same conditions. But it is not in heredity of functions or of organic or intellectual facts that the application of the law of heredity must be sought, but at the very fountain head of the organism, in its inmost constitution. A family whose head is insane or epileptic does not of necessity consist of lunatics or epileptics, but the children may be idiotic, paralytic, or scrofulous. What the father transmits to the children is not insanity, but a vicious constitution which will manifest itself under various forms in epilepsy, hysteria, scrofula, rickets, etc. This is what is to be understood by hereditary transmission." Physicians who deal with heredity often mar their results by limiting them to its direct effect.<sup>13</sup> Moreau indicated the line along which heredity should be studied when he divided the conditions due to hereditary defects into the following categories:<sup>2</sup> 1, absence of

conception; 2, retardation of conception; 3, imperfect conception; 4, monstrosities; 5, products, whose mental, moral, and physical constitution is imperfect; 6, products specially exposed to nervous disorders in order of frequency as follows: epilepsy, imbecility or idiocy, deaf-mutism, insanity, cerebral paralysis, and other cerebral disorders; 7, lymphatic products predisposed to tuberculosis and allied disorders; 8, products which die in infancy in a greater proportion than sound infants under the same condition; 9, products which, although they escape stress of infancy, are less adapted than others to resist disease and death.

For reasons already assigned the mother is the great factor in heredity. Genius seldom leaves posterity because it attracts hysterics and neuropaths as lighthouse lanterns do birds. Paternal heredity is a prophecy of what may be not a destiny. A healthy mother may offset the paternal defects of generation. Maternal environment involves the much mooted question of maternal impressions. The average reported photographic maternal impressions will not stand the scientific requirement that a given hypothesis to be accepted must not only explain all the facts but must exclude every other explanation. It has been claimed that maternal impressions do not occur among the lower animals. This, however, is offset by authenticated cases. Thus, there are still preserved in the British Museum specimens of "newly-hatched chicks with a curved beak like a parrot and the toe set back as in that bird. The hens in the yard where these monstrosities were hatched had been frightened by a parrot which, having escaped, fluttered among them before the eggs were laid, and greatly frightened the hens from whose eggs the malformed chicks are hatched." This case seems to support the photographic theory of maternal impressions. The fact is, however, these malformations are simple arrests of development. Birds are aberrant reptiles. During the egg period of development the chick passes through a reptilian phase. At the close of this period it begins to assume the more strictly avian characters. Arrest of development at the reptilian phase would produce the malformations described.<sup>6</sup> Just after impregnation a sow—in a case reported by T. C. Poole<sup>15</sup> of Mansfield, Texas—was scared by an elephant. One of the resultant pigs was elephantine in shape and proboscis. The pig's snout passed through an embryonic proboscis phase; this was, therefore, also an arrest of development.

These cases, however, demonstrate that mental shock may strongly assist remote atavism and produce arrest of development. The human fetus reacts very decidedly to sensory impressions on the mother. Women often in the midst of ordinary dreams producing but very moderate excitation, not generally interrupting sleep, are awakened by fetal movements. The dreams had nothing of the nightmare influence of a terrifying idea. They were merely the ordinary phenomena of sleep. Mental changes of the mother hence excite motor reaction in the fetus, and as with sensorial excitation these reactions are stronger in the fetus than in the mother. These motor reactions, as Féré points out, are obviously due to unconscious involuntary movement of the muscular walls of the womb.<sup>16</sup>

That maternal shock can exert an influence on the fetus there can be, therefore, no doubt. The question, however, as to the fact of this influence, its method of action, and its results, must be determined by an analysis of the period of pregnancy at which the shock is

charged and the result. Profound shock, destitution, and want of food act on the mother and may influence the fetus deleteriously. Hence the significance of the fact that 92 children born in Paris during the siege of 1870-71, 64 had slight mental or physical anomalies; the remaining 28 were all weakly; 21 were weak-minded; and 8 were subjects of moral imbecility. In Berlin the financial crisis of 1875-80 was followed by an increase in the number of idiots born. Not only do poverty and want produce anemia and malnutrition of the fetus, but profound shock disturbs the whole bodily metabolism. The nutrition of the mother may thereby be so disturbed as to result in a partial toxemia, which tends to disturb development of the fetus *in utero*. Thus a nexus of cause and effect can be traced. This influence is further borne out by the results of Dareste and E. C. Spitzka<sup>17</sup> in producing teratologic malformation. By wounding the embryonic and vascular areas of the chick's germ with a cataract needle, malformations are induced varying in intensity and character with the earliness of the injury and its precise extent. More delicate injuries produce less monstrous development. Partial varnishing or irregular heating of the egg-shell results in anomalies comparable to microcephaly and cerebral asymmetry. This latter fact (showing the constancy of the injurious effect of so apparently slight an impression as the partial varnishing of a structure not connected with the embryo at all directly) suggests the line of research to be followed in determining the source of the maternal and other impressions acting on the germ. What delicate problems are to be solved in this connection may be inferred from the fact that eggs transported in railroad cars, and subjected to the vibration and repeated shocks of a railroad journey, are checked in development for several days. A more delicate molecular transmission during the maturation of the ovum, during its fertilization, or finally during embryonic stages of the more complex and therefore more readily disturbed and distorted human germ, accounts for the disastrous effect of insanity, emotion, or other mental or physical shock of the parent on the offspring. The cause of the majority of cerebral deformities exists in the germ prior to the appearance of the separate organs of the body. Artificial deformities produce analogous results because they imitate original germ defects, either by mechanical removal or by some other interference with a special part of the germ. Early involvement of the germ is shown in the fact that somatic malformations in the hereditary psychoses often effect the body elsewhere than the nervous axis. The stigmata of heredity—defective development of the uro-genital system, deformities in the face, skull, irregular growth of the teeth, misshapen ears and limbs—owe their grave significance to this fact. Like deformities of the brain, these anomalies are also more marked and constant with the lower forms of the hereditarily based systematized perversions of the mind than the higher. It is easy from these results to understand how far and how the nervous system has its part in the disorders of general development. The individuals who present most deformities are equally those who suffer from most decided disorders of the nervous system.

In dealing with alleged defect from paternal heredity the influence of the father upon maternal environment must be taken into account. Epileptic children may result from the effect paternal inebriety has upon maternal health and environment. In cases of Calmuck idiocy charged to paternal drunkenness, healthy children

have been born despite the drunkenness until the mother has been broken down.<sup>18</sup> Drunkenness of the father at the time of impregnation may produce defectives through the resultant shock to the mother.

While the direct inheritance of minor defects is rare, its rarity is much overestimated. Prepuce absence among Jews is so frequent that a special volume of Rabbinical lore<sup>19</sup> deals with the controversies over the ritual to be used in case a child is born without a prepuce. The infrequency of such cases among non-circumcising races needs no demonstration. Ritual circumcision occurs during the formative stage of sexual development. The allegation of the absence of inherited effects from ritual circumcision is sheer assumption, repeated for decades without attempts at demonstration. The religious literature on the subject alone demonstrates this since theologians do not meet a ritual difficulty until it arises.<sup>20</sup> Tests of the malignity or benignity of heredity are often very erroneous. A large family is assumed to be decided evidence against degeneracy. It is often a transformation of malign heredity. As Herbert Spencer has shown, with increase in growth and specialization, decrease in the explosive manifestations of life must occur. Among these explosive manifestations in early biologic history is the function of reproduction which is common to all cells. With advance in evolution the functions of cells become specialized and the extent of reproductive power is decreased. This specialization Spencer designates individuation. In degeneracy the organism returns to the lower type and consequently tends to a reversion of individuation. From this results the plural and frequently repeated births in the phthisical and the degenerate. Valenta had under observation two epileptics (mother and daughter) who illustrated very decidedly the biologic stigma to which reference has just been made. The mother had thirty-eight children—six times twins, four times triplets, and twice quadruplets. The daughter at the age of 40 had had thirty-two children; three times twins, six times triplets, and twice quadruplets. Ninety families of degenerates coming under my own observation averaged eleven children each. Triplets, quadruplets, and twins were more than ten times as frequent as among the population taken as a whole. The occurrence of large families is not an expression of advance but of degeneracy. The teachings which have been entirely too prevalent as to the status in evolution being determined by progeny have cultivated what must be regarded merely as one transformation of malign heredity. Another biologic stigma of degeneracy on which considerable stress is laid as an evidence of health is the occurrence of one instance of old age in a family of short-lived people. In biology of degenerates such instances are remarkably frequent. In this instance, while there is an expression of healthy atavism, there is also an expression of degeneracy which, predisposing the organism to yield to slight causes of disease, thereby prevents it from being deeply affected by them. On the other hand the absence of any deep emotional feeling enables such an organism to ride through worry like a cork through an ocean storm, and thereby to survive.

It is obvious that the problem of heredity has been approached from the standpoint of preconceived notions. The forces underlying it have been estimated entirely from the standpoints of times when embryology and biology were unknown. Furthermore, certain forces have been regarded as malign or benign *per se* when circumstances made them so. The tests of malignity or benign-

ity have also been based on preconceived notions. Decrease or increase of births has been estimated entirely from a fallacious view-point.

## NOTE ON GAUGING VESICAL CAPACITY.

G. FRANK LYDSTON, M.D.

Professor of Genito-Urinary Surgery, State University of Illinois;  
Professor of Surgery, Chicago Clinical School.

CHICAGO.

The determination of the capacity of the bladder is often a very important point in the study and treatment of vesical disease. While the amount of urine that the bladder will retain without serious discomfort is by no means an infallible criterion of the extent of vesico-parietal pathologic alterations, it is nevertheless often of positive value from that standpoint. As indicative of the progress of certain cases under treatment it is often invaluable. As indicating the relative degree of impairment of elasticity of the bladder walls and the presence, degree and progress of pericystitis, the capacity of the bladder is one of the most important points for the consideration of the surgeon. The ordinary method of injecting the bladder hydrostatically—as with the fountain syringe or glass irrigating apparatus, with or without catheter or tube—is open to serious impeachment on the grounds of inaccuracy. The reasons for this inaccuracy I will venture to present.

1. In case the catheter or tube is used, the urinary *besoin* is excited by the presence of the tube in the deep urethra, vesical neck and cavity. Under these circumstances it is impossible to determine whether an imperative desire to urinate as the bladder is filled, is due to extreme physiologic distension, or to reflex excitation of vesical contraction through irritation of the seat of urinary desire by the catheter, which acts simply as might any foreign body.

2. When a large catheter is used, unless the hydrostatic pressure is too low to overcome the true sphincter and distend the bladder at all, the water rushes into the bladder so rapidly that the bladder is literally "surprised" into a reflex resentment of the inflowing fluid, and its capacity is transiently so diminished thereby that it is often less than half the normal capacity for urine. A bladder which will tolerate the presence of 8 or 10 ounces of urine under ordinary conditions often resents the pressure of 4 to 6 ounces of sterilized water by the irrigating method. When the urine trickles into the bladder *guttatim*, or enters *per saltum* from the ureters, the bladder is distended very gradually, and a relatively large amount of urine will be tolerated without discomfort. Half the same quantity of fluid thrown into the bladder rapidly will often necessitate immedi-

ate evacuation of the viscus. It would seem that bland and neutral urine should be better tolerated than the average acid normal urine, but I have made some very interesting observations on this point. In persons who are ingesting large quantities of pure spring water, which passes through the renal mechanism very rapidly, the bladder capacity is often immediately markedly decreased. This is due to the extreme rapidity with which the urine enters the bladder even though it be *per vias naturales*. I have noted this phenomenon so often that I feel sure of my ground. Irritable bladders can be, and often are, injuriously overworked in this way. When the hydrostatic method is employed without tube or catheter, the amount of force necessary to overcome sphincteric resistance forcoadains a relatively powerful, bulky and swiftly-running current. This awakens bladder resentment both from stimulation of the urinary *besoin*, and surprising the bladder muscle, and speedy evacuation becomes necessary. This explains why so few accidents happen from hydrostatic expansion of the bladder. The bladder contracts and expels the fluid before hyperdistension occurs. This protective reflex is, however, not to be trusted too far. Its reliability presupposes a fairly sound and fairly elastic bladder wall. Caution is therefore necessary in aged subjects, whether the bladder is known to be extensively diseased or not.

There is no routine method for measuring bladder capacity which is applicable to all cases. Symptomatically, cases may be divided into those in which the abnormal calls to urinate are worse at night, and second, those in which the greatest frequency is during the waking hours. In the first class of cases the symptom-producing condition is almost entirely organic. In such cases the environment of daytime life is more or less distracting, and the calls to urinate are not so frequent as at night. In the second class there is a greater or less degree of neuropathic disturbance, existing either as a complication of actual organic disease and subordinate to it, or constituting—as it often does—the overshadowing element of the case. It is often difficult to draw the differential diagnostic lines, it is true; yet the cases in which it can be done are by no means infrequent. In cases with a decided neuropathic bias, the patient is unduly concerned about his bladder symptoms, and as a result of auto-suggestion the frequency of urinary desire is increased. Few realize how important the neuropathic side of urinary disturbances often is. A physician of my acquaintance who is the unfortunate possessor of an irritable bladder, tells me that his condition is almost unbearable when he happens to have in hand cases in which the disturbance of micturition is a strong factor.

Even in cases in which the condition is obviously organic there may be a neuropathic element, as a consequence of which micturition is most frequent in the daytime. In general, however, increased diurnal frequency means conditions in which movement and gravity enhance the local irritation. This is often found in *prostatiques*, vesical tumor and calculus. In general, frequent micturition due chiefly to inflammatory conditions is improved by rest, nocturnal or diurnal.

In cases of a purely nervous type, or in which the nervous element is a serious factor for consideration—cases distinguished clinically by lessened frequency of micturition at night—and in certain organic conditions in which rest is productive of similar improvement in symptoms, the capacity of the bladder can be gauged

by a method at once simple and efficient, a method which does not err by proving only the capacity of the bladder while in hyperdistension. The patient should be instructed to drink moderately of pure water during the evening, and, when aroused at night by a desire to micturate, to pass water on each occasion in a separate vessel. The greatest quantity obtained at any given micturition represents the maximum capacity of the bladder from a clinical standpoint. Cases in which the frequency of urination is aggravated at night, can not be gauged in this way, and mechanical means must necessarily be employed. The chief source of error here is: 1. hyperesthesia of the prostatic urethra and consequent exaltation of the urinary *besoin*; 2. too rapid distension of the bladder, producing "surprise" and peremptory muscular reflex in the bladder wall.

These sources of error being understood, the practical deductions are at once obvious. In the first place, general reflex excitability, if marked, should be guarded against by sedatives and antispasmodics. A hypodermic of morphia, 20 to 30 minutes before gauging the bladder capacity, is very useful. The local reflex irritability may be done away with by applications of eucain or cocain to the prostatic urethra. A small catheter should be used, save in the exceptional instances in which sphincteric resistance is easily overcome and the hydrostatic method without catheter can be used under relatively low pressure. Sterile water or normal salt solution is best for distending the bladder. Antiseptic solutions, as a rule, are too irritating, and defeat the very purpose for which they are used.

Whenever, in gauging bladder capacity, the urine returns at first with some degree of force, but loses this force as the test proceeds, it may be safely assumed that temporary distension atony has been produced and the operation, so far as gauging vesical capacity at that particular *séance* is concerned, is a failure, and the test will require repetition.

100 State Street.

## PRIMARY SARCOMA OF THE ESOPHAGUS AND STOMACH.\*

WILLIAM TRAVIS HOWARD, JR., M.D.

Professor of Pathology, Western Reserve University; Pathologist to the Lakeside, City and Charity Hospitals.  
CLEVELAND, OHIO.

### PRIMARY SARCOMA OF THE ESOPHAGUS.

The fact that there are only eleven cases recorded in the literature shows that this affection is rare. Most of the cases have been regarded as pathological curiosities and were reported by the following authors: Chapman, 1877; Targett, 1889; Stephan, 1890; Shaw, 1891; Rolleston, 1893; Albrecht, 1895; Ogle, 1896; Livingood, 1898; Gastpar, 1900, and Stark, 2 cases, 1900. Besides these, Perry and Shaw, in an article on malignant tumors of the stomach, allude to two cases of sarcoma of the esophagus without, however, giving either clinical or pathologic data.

To the previously reported cases I am able to add another, that of a smooth muscle cell sarcoma of the lower end of the esophagus. The history is as follows: S. B., aged 51, was admitted to the Cleveland City Hospital service of Dr. Hoover, August, 1900, complaining of vomiting and difficulty in swallowing. He died a few weeks later of exhaustion.

\* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

*Clinical Diagnosis:* Carcinoma of the esophagus. Autopsy by Dr. Moore, resident pathologist.

*Anatomical Diagnosis:* Sarcoma of lower end of the esophagus, with metastasis in the cardiac end of the stomach, slight chronic interstitial nephritis, brown atrophy of the heart, emphysema and pigmentation of the lungs with broncho-pneumonia.

The body was 157 cm. long and markedly emaciated. The surface of the body was free from scars, abrasions and new growths. The superficial lymph glands were not enlarged. As the esophagus and stomach are the only organs showing lesions of present interest, the description of the other organs is omitted.

*Esophagus:* The organ is of normal size and appearance from its beginning to within 12 cm. of its cardiac end. At this point its wall is much thickened, and its mucous surface is the seat of irregular ulcers, covered with grayish necrotic material. The surface is irregular, but there are no polypoid masses projecting into the lumen. On section the wall is rather thicker than usual, firm and dense in consistency, and pale in color. The cardiac orifice of the stomach is narrowed, but admits the little finger with ease.

*Stomach:* The stomach is of ordinary size and appears normal throughout, except for the thickening of the cardiac orifice above described and for the presence near the latter of a nodular tumor, 7 cm. in its greatest diameter. On section this mass is seen to be beneath the mucosa. It is dense and firm and on section is glistening in appearance. Some of the lymph glands near the stomach are enlarged. There are no other metastases.

*Microscopic Examination of Esophagus and Stomach:* Sections made at various points through the wall of the esophagus, including the tumor, show in general the same appearances. The mucosa is fairly well preserved between the points of ulceration. In some places it is necrotic and contains numbers of bacilli, some of which are large and stout. In other places the mucosa is entirely replaced by a mass of fungoid tissue. It is composed of a fairly vascular fibrous tissue containing a number of larger and smaller areas of large spindle-shaped, large and small round, and many giant cells, which are supported by a variable amount of intercellular substance. There is no distinct alveolar structure, but a semblance of this occurs when masses of these cells occupy dilated vessels. The cells are often seen infiltrating the denser fibrous tissue. The nuclei of the tumor cells are large and vary much in shape, but are usually oval; they are often elongated, and even fusiform. They are usually vesicular and many of them contain fine chromatin granules. Some nuclei are dense and stain diffusely and deeply with hematoxylin and methylene blue. Some swollen nuclei contain small nucleoli. Nuclear figures are very numerous. The sarcomatous tissue is not diffuse, but, especially at the borders of the growth, occurs in patches. When, as is often the case, they occupy dilated lymph or blood vessels, the cells are usually large and often round, but even here long fusiform cells with long swollen vesicular nuclei are seen. In a few places the cells are arranged in concentric layers, and the cells of the inner layers are flattened and often show hyaline degeneration. The growth is best marked in the muscularis, all the coats of which are involved. (At the seat of the tumor only smooth muscle tissue is to be found.) In this tissue the most characteristic appearances of the growth are found. It consists of larger and smaller areas composed largely of long spindle-shaped cells with long swollen oval or fusiform nuclei. The cells and nuclei are often very large. The cells lie in parallel rows, usually separated by a small amount of intercellular tissue, which is, however, often absent or invisible. There is a striking resemblance between these cells and their nuclei and the muscle cells and nuclei of the neighboring tissue. The tumor cells nearest the muscle tissue very closely resemble those of the latter. They are narrower and have long oval or fusiform rather deeply staining nuclei. In most places it is easy to trace all gradations between the large tumor cells and the narrow muscle cells with thin deeply staining nuclei. The stages in the development of the muscle cells into tumor cells

is as follows: Along the advancing border of the growth the nuclei of some of the muscle cells swell and become more vesicular; later the nuclei become more swollen and develop fine chromatin growths. At the same time the cell body becomes thicker and its ends become somewhat rounded, and finally develops into a modified fusiform or even oval shape. Such cells can be found among unchanged muscle cells at quite a distance from the new growth. They are not infrequently found in isolated groups. In the sarcomatous tissue there are a number of large round cells with oval or round vesicular nuclei containing fine chromatin granules. Sections stained with Weigert's elastic tissue stain show little if any newly formed elastic tissue. As far as can be seen the fibrous tissue of the submucosa and of the muscularis plays no part in the tumor formation. Many of the larger sarcomatous areas show marked necrosis, with nuclear fragmentation. In the tumor tissue and at its border there are numerous polymorphonuclear eosinophiles. This tumor, then, is a mixed cell sarcoma apparently divided solely from the smooth muscle tissue of the esophagus.

Sections of the wall of the stomach made through the nodule show atrophy and superficial necrosis of the mucosa, which is entirely lost in places. In other places it is infiltrated with small round cells. The submucosa is in general free, but here and there shows the same round cell infiltration. The muscularis is the seat of an extensive invasion of a new growth in every way similar to that described in the esophagus. In most places the tumor cells are situated in dilated vessels. In some places the tumor tissue infiltrates the muscularis and a number of areas are to be seen in which the muscle cells take part in the tumor growth and show the same changes noted in the esophagus. In many of the muscle cells near the new growth there are large vacuoles.

Sections of the enlarged lymph glands show a new growth similar to that of the esophagus and stomach. There is, however, marked necrosis.

*Revised Diagnosis:* Primary myosarcoma of the esophagus, with metastases in the stomach and neighboring lymphatic glands.

Until Livingood's paper, in 1898, sarcoma of the esophagus was regarded as a pathologic curiosity and, on account of its rarity, of no special clinical importance. Livingood analyzed the cases reported to the date of his article and added a well-studied case with a full clinical history. He concludes that there is clinically no essential difference between sarcoma and carcinoma of the esophagus. He further notes that the advance of sarcomatous tumors of the esophagus is more rapid than carcinoma, being fatal within nine months from the first symptoms; that widespread metastases and the location of metastases are as uncommon and indefinite as in carcinoma, and finally, that the mode of termination is the same in both. Livingood found eleven cases of carcinoma and one case of sarcoma of the esophagus in one thousand consecutive autopsies. He suggests that the apparent rarity of sarcoma is due to a lack of careful histological study of esophageal tumors.

Stark, in the most recent and complete article on esophageal sarcoma, reports two cases and analyzes the clinical symptoms of the affection. In regard to the differential diagnosis between sarcoma and carcinoma of the esophagus, he states that age has little influence if the case of Stephan (a 4-year-old child) is excepted, but that in an individual under 25 years of age sarcoma is much more probable than carcinoma. He thinks that the most important symptom is pain, which in carcinoma may be lacking for months, and when it does occur is rarely of the intense stabbing character observed in sarcoma; the pain in carcinoma is usually most marked after eating, and in sarcoma while fasting, especially at night. He further states that the pain in sarcoma is

back between the shoulder blades, which is uncommon in carcinoma. He also points out that the duration of the disease is shorter in sarcoma; in one of his cases death occurred in ten weeks after the first symptoms of dyspepsia.

A critical study of the twelve recorded cases (including my case) of sarcoma of the esophagus brings out the following information:

*Age.*—Youngest, 4 years (lympho-sarcoma, Stephan); 25 years, one case; 38 years, one case; 41 years, one case, 45 years, one case; 50 to 55 years, five cases, and 60 to 70 years, two cases. (The cases of Perry and Shaw are mentioned without clinical or pathological data and are, therefore, useless for generalization.)

*Situation of the Tumor.*—Lower part of the esophagus, 9 cases; upper part, 2 cases; not mentioned in 1 case.

*Morphology of the Tumors.*—Pedunculated or polypoid in 3 cases (Ogle, Albrecht and Stephan); diffuse tumor formation with polypoid or nodular excrescences in 2 cases (Livingood and Gastpar); tumor mass completely surrounding the lumen in 3 cases (Rolleston, Gastpar, Stark—2 cases—and Howard); not mentioned in 3 cases. More or less obstruction occurred in nearly all cases; in some stenosis was complete. Ulceration of the mucosa and of the growths occurred in 7 cases. Perforation of the esophagus occurred in 4 cases; into the trachea twice. (Shaw and Livingood); and with pleurisy and lung inflammation twice (Rolleston and Stark).

*Histologic Characters of the Tumors.*—Lympho-sarcoma, 1 case (Stephan); round cell sarcoma, 4 cases (Shaw, Stark, Rolleston); pure spindle cell, 2 cases (Ogle and Livingood); oval and spindle cell, 2 cases (Chapman and Targett); alveolar, 1 case (Albrecht). Large mixed cell, 1 case (Gastpar); muscle cell, 1 case (Howard).

*Metastases* were noted in 5 cases; in the neighboring lymph glands, stomach, intestines, kidneys, adrenals, lungs, liver, brain, etc., in 1 case (Stark); in the peripancreatic lymph glands, the iliac bone and neighboring muscles, the temporal bone and muscle, 1 case (Rolleston); in the neighboring lymph glands and kidneys, 1 case (Shaw); in the stomach and gastro-hepatic lymph glands, 1 case (Howard); and in the liver, 1 case (Stark).

In one of Stark's cases the stomach contents were acid in reaction, without, however, the presence of free HCl.

In 4 cases, no clinical diagnosis was made; in 3 cases it was carcinoma, in 3 esophageal tumor; in one case periostitis of the spinal vertebrae with extension to the esophagus, with perigastritis; in 1 case there were no clinical symptoms referable to the esophagus. In this case—Albrecht's—the patient died of croupous pneumonia and at autopsy a pedunculated alveolar sarcoma was found in the esophagus.

*Conclusions.*—Analysis of the twelve recorded cases of sarcoma of the esophagus shows the following: 1. The disease is more common in males than in females, and at the period of life during which carcinoma most frequently occurs. It may, however, unlike carcinoma, occur in early life—between 4 and 25 years. 2. Nine of the twelve cases involved the lower half of the organ. 3. While the tumors usually nearly surround the lumen, in three cases they formed pedunculated or polypoid masses projecting into the lumen. 4. Symptoms of esophageal obstruction occurred in eleven of twelve cases. 5. There was perforation with involvement of the respiratory organs in four cases. 6. All the varieties of sarcoma except angio-sarcoma have been found, the round cell variety standing first in frequency—one-fourth of the cases. 7. Metastases occur rather frequently (five out of twelve cases), and in two cases were widespread. 8. The clinical diagnosis of esophageal sarcoma has not been made and there are no certain and constant diagnostic points between sarcoma and carcinoma of this organ, the clinical symptoms being neces-

sarily very much the same and dependent upon the same conditions—obstruction and cachexia—in the two diseases. 9. As pointed out by both Livingood and Stark, sarcoma runs a more rapid course, and a fatal issue is to be looked for earlier than in carcinoma. The greater size of the sarcomatous growths is probably responsible for this. 10. The differences in the character, distribution, and period, of the pain in the two affections described by Stark, are not mentioned by other observers. It would prove a matter of considerable importance if his experience is confirmed.

#### PRIMARY SARCOMA OF THE STOMACH.

A case of sarcoma of the stomach was recognized and reported as early as 1847 by Bruch, and Virchow described three cases in 1865. Although a considerable number of cases were reported chiefly as pathologic curiosities, it was not until the classical article of Schlesinger, in 1897, that the subject assumed clinical importance. This author reported three personally observed cases and collected 33 others from the literature. In 1898 Brooks reported a case and analyzed 15 others which he collected from the literature. In the past six years several cases have been reported by surgeons—Hartley, Baldy, Capello, Cantwell and others—who have removed gastric sarcomata at operation. The best of the recent articles on gastric sarcoma is that of Dock, in 1900, who reported a carefully studied case, and collected 13 additional cases from the literature, which, added to the cases collected by Schlesinger, brought the total number of known cases up to 50.

In a careful search of the literature I have been able to add 7 cases to these, which, together with the 4 cases reported in this article, increase the total number of cases to 61. I have taken considerable pains to criticize the accuracy of the diagnosis in the cases collected from the literature and have excluded all those in which there was any apparent doubt in regard to the correctness of the diagnosis of sarcoma. As several of the reported cases have been found by accident in articles under other titles, I am led to believe that this list does not include all the recorded cases. All who write on the subject must acknowledge a debt to Krüger, Schlesinger and Dock. The disease is ignored in most of the textbooks on diagnosis, diseases of the stomach and pathology.

*CASE 1.*—Diffuse round cell sarcoma with atrophy and constriction of the stomach.

Female, aged 65 years, a patient of Dr. J. H. Lowman, to whom I am indebted for the clinical history, complained of nausea and vomiting for over a year before her death, which occurred Jan. 12, 1896. She was weak and emaciated, but was able to walk about the room three days before her death. No mass could be palpated in the abdomen.

*Clinical Diagnosis:* Carcinoma of the stomach.

*Autopsy:* The body was that of a woman of ordinary size, and was poorly nourished. The abdomen was distended. The skin showed no scars, abrasions or new growths. The pericardium, heart, aorta and large vessels showed no abnormalities. The esophagus was normal.

*Stomach:* The stomach occupied its usual position. It was very small, being about one-fourth its ordinary size. On external examination it was everywhere hard, firm and inelastic. Midway between the cardia and pelvis the organ was markedly constricted, roughly resembling an hour-glass in shape. On section its wall was everywhere greatly thickened, being from 1 to 3 or 4 cm. in thickness. At the point of constriction the lumen was 3 cm. in diameter. The mucosa, which was of a brownish-red color, was unbroken. The thickening of the stomach wall was due to the presence of a dense and firm grayish-white tissue, which had a rather homogeneous

appearance. This tissue apparently did not encroach upon the mucosa, but involved the submucosa and muscularis, both of which coats were extensively infiltrated. The gastro-hepatic, mesenteric and retro-peritoneal lymph glands were enlarged and had the same appearance as the growth in the wall of the stomach.

The other organs showed nothing of present interest.

Sections of the stomach made of various portions showed in some places disintegration of the mucosa. In some places it had entirely disappeared. In all the sections examined, the submucosa was transformed into a fibro-cellular tissue composed of newly-formed fibrous tissue containing variable numbers of small round and oval cells. The cells showed no special arrangement, but often occurred in groups and masses and were always supported by fibrous tissue or by a fibrillar intercellular substance. The individual cells varied from 8 to 15 mikron in diameter. They had a single round or oval nucleus which usually stained deeply and uniformly with hematoxylin. Some cells had paler nuclei. The cell bodies were usually round or slightly oval. A few spindle-shaped cells were seen. In all sections the muscularis was markedly invaded, in many places diffusely. All grades of invasion of this coat occurred from small islands of tumor cells to complete transformation into tumor tissue. The muscle tissue was pushed aside and infiltrated by the new growth. There was no evidence of proliferation of the muscle cells, which, so far as could be determined, played no part in the tumor formation. The origin of the tumor from the fibrous tissue of the submucosa was clear. A few blood vessels were found in the new growth. In no places was invasion of blood vessels made out. The amount of fibrous tissue present in some parts of the tumor warrants the term fibro-sarcoma. Sections of the lymph glands showed a growth in all respects similar to that of the stomach.

*Anatomic Diagnosis:* Small round and oval cell sarcoma of the stomach, primary in the submucosa, and infiltrating the muscularis. Constriction producing hour-glass shape of the stomach. Secondary sarcomatosis of the gastro-hepatic mesenteric and retro-peritoneal lymph glands. Anemia.

**CASE 2.**—Mixed cell sarcoma of the stomach with abscess formation in the tumor, with metastases in the neighboring lymph glands.

R. F., female, aged 46 years, was admitted to the Lakeside Hospital, Sept. 7, 1898, service of Dr. Dudley P. Allen (Dr. Nevison acting), complaining of anorexia, headache, pain, swelling in the region of the spleen. There was no vomiting and no pain in the epigastric region. A large mass could be felt in the region of the spleen. Examination was otherwise negative. The urine contained a trace of albumin but no casts. The red blood cells were normal in number and appearance. A considerable leucocytosis was noted.

*Clinical Diagnosis:* Tumor of the spleen. The patient died 12 days after admission. Autopsy a few hours after death.

*Anatomic Diagnosis:* Primary mixed cell sarcoma of the stomach with abscess formation and peritonitis. No metastases. Edema and congestion of the lungs. Adenoma of the duodenum. Streptococcus pyogenes and staphylococcus pyogenes aureus, and a short liquefying bacillus in the peritoneal exudate and abscess of the tumor of the stomach.

The body was 172 cm. long. The general nutrition was good. There were no scars, wounds or growths upon the surface of the body. There was bilateral enlargement of the thyroid. The chest was well shaped, the pleura negative; the lungs showed congestion, edema and emphysema, but were free from tumors. The pericardium, heart and aorta are without present interest. The abdomen was distended and very tympanitic. The abdominal wall contained a thick layer of fat; the muscles were pale. The parietal peritoneum was covered with a thin fibrino-purulent exudation. The coils of the intestine were bound together by recent fibrous adhesions, containing larger and smaller collections of creamy pus. The liver projected 4 cm. below the costal border in the mammary line. The under surface was adherent to the stomach, and the colon. The stomach was intimately bound to the surrounding

structures, and was displaced downwards towards the left, so that its posterior surface lay over the left kidney. Its anterior wall was of ordinary size and appearance. The posterior wall was thickened. On the right side there was a ragged opening, 8x4 cm., between the peritoneal cavity and with a large cystic area in the posterior wall of the stomach.

*Stomach:* On removal and section the stomach contained foul-smelling yellowish material. The cubic capacity of the organ was reduced, while its bulk was markedly increased. The anterior wall was normal in appearance. Near the lesser curvature, and affecting nearly the whole of the posterior wall, there was a tumor mass 20x16 cm. which varied from 0.5 to 8 cm. in thickness. Near the lesser curvature there was a fungus-like mass, 6x8 cm. in breadth and length, which protruded into the lumen of the stomach. This protuberance was irregular in outline and ulcerated, and covered with a foul-smelling yellowish pus. The tumor did not extend to or involve the pylorus, which was quite soft. The tumor lay beneath the mucosa everywhere except at the ulcerated area. At the cardiac end of the tumor there was a cyst 7x4 cm., and at the pyloric end a similar cyst 6x5 cm.; between these there was a larger cyst, communicating with the other two. These cysts contained fluid and necrotic material. The larger cyst communicated with the peritoneal cavity. The tumor varied very much in thickness, the cyst walls being from 1 to 3 cm. thick. The tumor involved the submucosa and invaded the muscularis and mucosa irregularly. On section it varied much in consistency, in some places it was soft, while in others it was dense and firm. On the right side of the stomach near the tail of the pancreas, there was a nodular mass, apparently an enlarged lymph gland, measuring 8x4 cm., which on section had the same appearance as the growth in the stomach, and contained a cyst 3x2 cm. in size. The neighboring lymph glands were swollen. The posterior wall of the stomach was bound to the pancreas, which was not, however, invaded by the tumor. The duodenum was markedly congested; 8 cm. below the pylorus there was a small nodule, 1.5 cm. in diameter, situated in the submucosa. The rest of the intestines showed nothing abnormal. The other organs showed nothing of present interest.

Sections of the stomach made at a distance from the tumor showed nothing abnormal. Sections from various portions of the tumor all showed much the same structure, the tissue being composed of rather large round, oval and spindle-shaped cells of the connective-tissue type, and with relatively large nuclei. The cells were not arranged in alveoli, but a supporting connective-tissue could be made out. In some places, especially at the borders, the tumor was fibro-cellular, while in others it was markedly cellular in structure. Larger and smaller areas of necrosis were found. Sections taken from the margins of the cysts showed marked necrosis, with nuclear fragmentation. In this material there were large and small clumps of large bacilli. In a few places there was an intimate relation between the tumor cells and the adventitia of arteries and veins, suggestive of the vascular origin of the former. These areas were always isolated. In other places, at a considerable distance from the main tumor, there were small irregular islands of typical sarcoma tissue and apparently springing from the connective tissue of the submucosa. The tumor was situated in the submucosa and invaded the muscularis and the mucosa in only a few places. Its origin was without doubt in the submucosa. Sections of the smaller tumor showed the same structure met with in the larger. No trace of lymphatic tissue, however, remained. There was markedly little inflammatory reaction about and in the tumors of the stomach; no groups of tumor cells were found in either blood or lymph vessels. Some of the veins, however, contained recent thrombi.

Sections of the small tumor situated in the submucosa of the duodenum showed a typical adenoma, composed of a large number of glands divided into lobules by connective tissue bands. The glands were lined with a single row of epithelial cells, which were columnar in some and cuboidal in other glands. The cytoplasm of these cells was finely granular and stained poorly; the nuclei were vesicular and placed at the base of the cells, where the latter were supported by a delicate membrana

propria. The epithelial cells formed a single row in the glands and never broke through the membrana propria. No ducts were to be found. The tumor lay almost entirely in the submucosa, but in some places had pushed through the muscularis mucosæ and encroached upon the mucosa, which was normal in appearance. Sections of the tumor of the thyroid showed a papillary adenoma. The other organs are without present interest.

CASE 3.—Sarcoma of the pylorus. G. H., white, a laborer, aged 48 years, was admitted to St. Alexis' Hospital, service of Dr. Cogan, Oct. 26, 1900, complaining of vomiting and weakness. His family history was negative. The patient stated that he had always enjoyed good health until December, 1899, when his appetite failed and he began to lose weight. In October, 1900, he had to give up work on account of weakness and discomfort in his stomach. At this time he began to vomit after each meal. After admission to the hospital he vomited almost continuously until his death, which occurred on November 3. No food could be retained by the stomach.

Examination of the chest was negative. No tumor could be felt in the abdomen. On testing the stomach contents the acidity was normal. Motility and absorption were both diminished. The red blood cells numbered 1,000,000 per cubic millimeter. The leucocytes were not increased.

*Anatomic Diagnosis:* Sarcoma of the pylorus and neighboring portion of the stomach. Broncho-pneumonia of both lungs. Chronic adhesive pleuritis. Anemia.

The body was poorly nourished. Rigor mortis was present. The other organs showed nothing of present interest; only the description of the stomach is taken from the autopsy protocol.

*Stomach:* This was somewhat dilated. On opening the organ the pylorus and the wall of the stomach on all sides for a distance of 10 cm. from the pylorus, were found to be thickened. The mucosa was unbroken. The gastric wall at the pylorus measured from 1 to 2 cm. in thickness. The tumor on section was at nearly every point beneath the mucosa, and its chief seat was the submucosa, but in many places it could be traced into the muscularis. The tumor was homogeneous in appearance and firm in consistency. The lymph glands in the neighborhood of the stomach were not enlarged. No metastases were found in any organ.

In sections made from various portions of the tumor the mucosa was atrophied, the tubules having been compressed and the interglandular stroma replaced by fibrous tissue containing, round, oval or fusiform cells. The muscularis mucosæ was absent in many places. The submucosa was everywhere thickened, due to a new growth of fibrous tissue, containing a varying number of fusiform, round and oval cells, supported by a variable amount of intercellular substance. At many places this tissue extended into the muscularis. In some places the sarcomatous tissue was markedly fibrous. Throughout the tumor the capillaries were numerous. In many places the lymph vessels were dilated and contained tumor cells. In some places the endothelial cells of the lymphatics showed marked proliferation and nearly filled the lumina of these vessels. In some lymphatics the lining cells had assumed a cuboidal shape and the structure had the appearance of a tubular gland. The new growth in some places invaded the nerves and even the serosa. There was no peritonitis.

CASE 4.—A saloonkeeper, aged 39 years, married and a moderate drinker, suffered with occasional attacks of indigestion and discomfort in the epigastrium for a year before consulting Dr. Robert H. Sunkle, to whose kindness I am indebted for the history and autopsy in this case. When first seen by Dr. Sunkle, the man complained of pain in the abdomen, loss of weight, strength and appetite. The liver was greatly and uniformly enlarged, but no nodules were palpated. No tumor could be made out in connection with the stomach. The heart and lungs were negative. There was occasional vomiting, but no special pain referable to the stomach.

A few days before death, which occurred one month after Dr. Sunkle first saw the case, dulness was made out in the flanks. Dr. Sunkle's diagnosis was hypertrophic cirrhosis of the liver, in which he was upheld by Dr. Sihler, who saw the case in con-

sultation. Later the possibility of carcinoma of the liver was considered.

The autopsy was made by Dr. Sunkle, who brought the organs to my laboratory for examination.

*Anatomic Diagnosis:* Primary angio-sarcoma of the lesser curvature of the stomach, with metastases in the neighboring lymph glands and in the liver.

As the stomach and liver were the only organs showing changes of present interest, a description of the other organs is omitted.

*Stomach:* The organ was of ordinary size. The lesser curvature was thickened. On section, the cardiac and pyloric ends were normal, as were the greater curvature and the anterior and posterior walls. The mucosa was somewhat thickened. The whole length of the lesser curvature was thickened and from it a mass of tissue protruded into the cavity of the organ. The mass was from 1.5 to 2 cm. in thickness and 4x5 cm. in outline. The surface was irregularly ulcerated and it was difficult to make out the mucosa. On section the mucosa was soft, readily lacked the pearly translucency of carcinoma. The growth extended through the coats of the stomach, and included and surrounded several enlarged lymph glands, which were virtually involved in the growth. On section these glands were soft and had the same appearance as the gastric tumor. The peritoneal cavity contained a considerable amount of clear fluid. There was no peritonitis. The liver was markedly enlarged, its edges rounded, the capsule mottled red and yellow. Scattered over the surface, but lying well beneath the capsule, there were a number of soft yellowish areas. On section both the right and left lobes of the organ were the seat of numerous grayish-yellow areas of soft consistency, sharply marked off from the surrounding liver tissue, and varying from 0.5 to 3 or 4 cm. in diameter. Many of the large branches of the portal vein were occluded by grayish-yellow masses, which were here and there mixed with blood and coagula. Portal vessels could be traced into many of the larger masses, which often contained central hemorrhagic areas. The liver tissue between the masses was congested and in places compressed. The external surface of the gall bladder showed a small nodule similar to those found in the liver. The gall bladder and bile ducts on section were normal. The mesenteric glands and other organs were free from metastases.

*Histologic Examination:* Stomach. In sections of the gastric wall made at a distance from the tumor, there was disintegration of the superficial layer of the mucosa. In sections cut through the tumor at various places the mucosa showed disintegration to a varying depth. In some sections the deeper layers of the mucosa were invaded by tumor tissue which compressed and replaced the tubules and interglandular tissue. The submucosa was markedly thickened, due to the presence of large areas of tumor tissue which was diffuse in some places and in others sharply circumscribed. This latter appearance was usually due to the extension of tumor tissue into large and small veins. The tumor evidently had its origin in the submucosa and varied in structure considerably. In many places the structure was typical of a mixed cell sarcoma, being composed of large and small round and oval cells, large spindle-shaped and numerous giant cells, and a variable amount of intercellular tissue, which was conspicuous in some places and scanty in others. In general, the tumor was very cellular. In all parts of the growth, capillaries, most of which contained blood, were numerous. In most places the relation of the tumor cells to the capillaries was intimate, viz., masses of round, oval, flattened and often fusiform cells surrounded blood capillaries, and were placed directly in relation with their walls. In some places, especially in the metastases in the liver, tumor cells were arranged in a regular row about a small lumen, in such a manner as to resemble a cross-section of a tubule. Blood cells and granular material were present in some of these spaces. In still other places the tumor cells were arranged in large alveoli, supported by a variable amount of intercellular tissue and capillaries. The muscularis was only slightly invaded, and the mucosa was markedly invaded in places. The invasion of the large and small veins of the sub-

mucosa was marked. Most of these vessels in the tumor area were completely occluded by tumor tissue, similar to that above described. The tumor cells varied much in size and shape. Their nuclei were large, round or oval, some staining densely, while in others fine chromatin masses could be made out. In many nuclei there was a rather large oval or round hyaline body, which stained pink with eosin. Nuclear figures were common. The giant cells had very large single nuclei. Many of the tumor cells showed marked fatty degeneration. The growths in the lymph glands and the liver were identical with that of the stomach. The relation of the tumor cells to the capillaries was especially well marked in the liver metastases. Some of the branches of the portal vein contained both tumor cells and fibrinous thrombi. Many were completely occluded. In many places the new growth in the liver had passed through the veins and was infiltrating the liver tissue. In sections some distance from metastases, there was marked necrosis of the central portions of the liver lobules with hemorrhage. There could be no doubt in regard to the sarcomatous nature of the neoplasm, which evidently sprung from the blood vessels of the submucosa of the stomach.

*Frequency.*—The disease is certainly rare, but probably occurs more commonly than is generally supposed. There can be no doubt but that in the absence of routine microscopic examination of tumors found at operation and autopsy, many cases must have been mistaken for carcinoma, which, indeed, was the clinical diagnosis in a considerable number of the recorded cases. So far there are sixty-one known cases. Next to carcinoma it is certainly the most common tumor of the stomach.

*Etiology.*—Of the 61 cases 30 occurred in females, 25 in males and in 6 the sex was not mentioned. In regard to age the youngest reported case occurred in a girl 3½ years old (Findlayson's lympho-sarcoma). The age was reported in 52 cases and the ages were as follows: It was from 15 to 20 years in 6 cases; 20 to 30 in 9 cases; 30 to 40 in 7 cases; 40 to 50 in 10 cases; 50 to 60 in 10 cases; 60 to 70 in 5 cases; 78 in 2 cases, and given as "old age" in 2 cases. Nothing is known of the primary cause of the disease. In Brooks' case the tumor started in an old bullet wound of the stomach.

*Seats of Tumors.*—Heretofore on account of the meager data at hand little attempt has been made to establish the principal seats of sarcoma of the stomach. Schlesinger and Dock concluded that any portion of the gastric wall might be affected. The former states that the greater curvature is the most common seat, especially of the nodular form, while lympho-sarcomata are apt to be diffuse. Dock calls attention to their origin at the pylorus and in the posterior wall in some of the recently reported cases.

Analysis of the 61 cases shows that the growth was diffuse in 13, of which 4 were lympho, 5 round cell, 1 fibro and 1 spindle-cell sarcoma. In 8 cases the growth was limited to the pylorus, in 6 cases the pylorus and the lower half of the stomach were involved, in 1 the pylorus and the upper part of the duodenum, and in 1 the pylorus and the greater curvature; the pylorus was involved in a total of 16 cases. The tumors were primary in the greater curvature in 7 cases, and involved the greater curvature with the posterior wall in 1 case, with the lesser curvature and posterior wall in 2 cases, and with the anterior wall in 1 case, making the total involvement of the greater curvature 11 cases. The lesser curvature alone was involved in 5 cases, with the cardia in 3 cases, with the posterior wall in 1 case and with the posterior wall and greater curvature in 1 case. The posterior wall alone was affected in 6 cases, and with the anterior wall in 1 case. The cardia was involved in only 3 cases, and always with the

lesser curvature. The anterior wall was never involved alone, but was affected with the posterior wall in 1 case, and the greater curvature in another.

It is seen from the above that the growth involved the pyloric end in a total of 16 cases, the cardiac end in 3 cases, the intermediate portions in 27, while it was said to be diffuse in 13 cases. The seat of the growth was not mentioned in 5 cases. The stomach and whole gastro-intestinal track were involved in 1 case of lympho-sarcoma.

Pyloric stenosis was noted in only 5 cases, but probably occurred more frequently, for the reports are meager in many instances.

*Size of Tumors.*—They were stated to have been the size of a pigeon's egg in 1 case, a man's fist in 2 cases, an orange in 1 case, a child's head in 5 cases, and a man's head in 6 cases. The tumors extended below the umbilicus in 8 cases.

*General Appearances.*—They were said to have been nodular in 27 instances, and in some of these, notably in 2 cases, the tumors formed polypoid masses projecting into the lumen of the stomach. Tumors projected into the peritoneal cavity in 8 cases. In some of the latter cases the base of the tumor was narrow. The new growths showed ulceration in 10 cases, with perforation of the gastric wall in 2 cases.

In many instances, the exact number of which could not be determined, the growth developed beneath the mucosa, which was intact. The growth usually started in the submucosa, and the muscularis was commonly involved. The tumors occasionally had their origin in the muscularis, and cases of myosarcoma was recorded.

The tumors varied much in consistency, from soft, spongy, fungoid masses to firm, fibrous growths, and had the general macroscopic characters of sarcoma of other organs. They differed from carcinoma in their situation, being usually beneath the mucosa and often not involving the latter, and also in their nodular character, comparative dryness and homogeneous appearance on section. In many cases the diagnosis was not made until microscopic examination. This was, no doubt, often due to lack of care in the macroscopic examination. Cystic degeneration of the tumors occurred in 6 cases, hyaline degeneration in 1, calcification in 3, myxomatous degeneration in 2, and suppuration in 1. The stomach is stated to have been decreased in size in 2 cases, and in 1 case, the second reported in this paper, it was constricted in the middle and resembled an hour glass in shape. In a few cases, dilatation of the stomach is mentioned, but this seems to be much less common and not so marked as in carcinoma. It will be noted that the pyloric end of the stomach was involved in only 16 out of 61 cases—26.23 per cent.—and that pyloric stenosis was noted in only 5 cases—8.19 per cent. The stomach was bound to the right lobe of the liver in one case and the spleen in another.

*Involvement of Other Glands.*—Metastases occurred in 24 cases—40 per cent.—a smaller proportion than in carcinoma. The gastro-hepatic lymph glands were involved alone in 2 and with other organs in 5 cases; the mesenteric glands in 6 cases, never alone; the retroperitoneal glands alone in 1 case and with other organs in another. The omentum was invaded in 2 cases, the liver in only 7 cases, the spleen in 4, the kidneys in 2, the ovaries in 3, the peritoneum in 2, and the intestines, pancreas, thyroid, right adrenal, and testis each in 1 case. In our Case 4 there was extensive sarcomatous

embolism of the branches of the portal vein, with multiple large metastases of the liver.

*Histologic Classification.*—The growths were classified as round cell in 16 cases, spindle cell in 8, mixed cell in 4, as lympho-sarcoma in 15, myosarcoma in 4, fibro-sarcoma in 3, angio-sarcoma in 3, and endothelial (lymph) sarcoma in 1. The histologic diagnosis was not given in 7 cases. In Case 4 of our series giant cells were numerous.

*Clinical Symptoms.*—Reigel states that there is no clinical difference between sarcoma and carcinoma of the stomach, and that hematemesis and cachexia are common to both. Schlesinger found that examination of the stomach contents (7 cases reported by Hammerslog, Maass, Dreger, Fleiner and Schlesinger) showed nothing essentially different from that of gastric carcinoma. Dock, who has presented the most carefully studied case, made a diagnosis of dilatation from a tumor at the pylorus, probably the scar of an old ulcer, but also thought of carcinoma and sarcoma, "but the features of the case were not considered to admit a differential diagnosis."

According to Reigel the clinical course runs from a few months to three years, on an average of from 1 to 1½ years. In several cases death occurred within from four to six months from the onset of nausea and vomiting and epigastric pain. Many cases run their course without symptoms until near the end. Case 4 illustrates this point. In some cases there were no clinical symptoms referable to the stomach. In Hartley's case there was coffee-ground vomit and dyspepsia five years before the case came under observation. There was no recurrence and except for symptoms of indigestion, fair health was enjoyed for four years, when coffee-like material was vomited on five successive mornings.

Analysis of the cases shows that the duration of the illness was mentioned in only 16 cases as follows: Six weeks, 1 case; 3 months, 1 case; 5 months, 1 case; 7 months, 1 case; 9 months, 1 case; 1 year, 4 cases; 2 years, 1 case; 3 years, 1 case; several years, 1 case; 5 years, 1 case. Vomiting was recorded in 18 cases, in 4 of which the vomitus was bloody. Loss of appetite was recorded in 5 cases, but was probably a common symptom. Diarrhea was a marked symptom in 2 cases, but constipation seems to have been of frequent occurrence. Pain in the gastric region was complained of in 6 cases; pain in the abdomen was noted in 9 cases, in 3 of which it dated for 2 years.

Tumors were palpated in the gastric region in 10 cases, in the splenic region in 6, and in the lower abdomen in 13 cases. In Case 4 the liver was enormously enlarged with no symptoms suggestive of disease of the stomach. Emaciation was noted in 13 cases.

The condition was mistaken for pseudo-leukemia in 1 case, and for pernicious anemia in 1 case; ascites occurred once and jaundice twice. Dock found that the blood in the cases of gastric sarcoma previously reported showed a decrease in the hemoglobin and in the number of red blood cells, and usually leucocytosis.

*Diagnosis.*—A diagnosis was either not made or not mentioned in 38 cases. In 5 cases a diagnosis of gastric carcinoma is recorded; in 8 cases the diagnosis was "neoplastic tumor" of the stomach, while a positive diagnosis of sarcoma of the stomach was made in 3 cases, by Schlesinger, Reigel and Westphalen. In the first the diagnosis was made on the microscopic examination of a bit of tissue obtained on washing the stomach. In the second case a large sarcomatous nodule

was vomited. A probable diagnosis of an old scar of the pylorus was made in one case by Dock. The diagnosis was tumor of the spleen, tumor of the omentum, tumor of the left hypochondrium, cystic tumor of the abdomen, ovarian cyst and pseudo-leukemia, each in one case. In Case 4 the diagnosis was hypertrophic cirrhosis of the liver. Little mention is made of differential diagnosis in the literature, and Dock undoubtedly states the case correctly when he says, that so far as the earlier stages are concerned we have no specific symptoms of sarcoma of the stomach and even when a tumor is present (palpable) it can not be differentiated from cancer (carcinoma). As previously pointed out, analysis of the gastric contents has hitherto been of no aid in differential diagnosis between gastric sarcoma and carcinoma.

Analysis of the 61 cases at our disposal brings out several points which may be of assistance in a differential diagnosis between sarcoma and carcinoma after the presence of a gastric tumor is established. In the first place age has an important bearing. It was shown to be as follows: One case of lympho-sarcoma of the stomach occurred in a girl 3½ years old; 7 were below 20 years; 23, or 37.7 per cent., were below 40, and only one-third of the cases occurred between 40 and 60 years, the most common period for the occurrence of carcinoma of the stomach.

In 16 cases, or 26.23 per cent., the tumors were situated at the pyloric end, causing pyloric stenosis in only 5 cases. In but 3 cases was the cardia involved. In the other 41 cases the tumors were seated between the pylorus and cardia, without involving either. These facts are not, however, of as much assistance as they seem at first glance, for it is chiefly in the cases in which the ends of the organ are involved, that symptoms of gastric tumor occur. The growth was diffused over the surface of the organ in 13 cases. Accurate figures could not be obtained, but it is clear from reading the reports of the recorded cases that dilatation of the stomach is much less common in sarcoma than in carcinoma of the stomach. In several cases the stomach was decreased in size. Gastric sarcoma was mistaken for tumor of the spleen or splenic region in 3 cases, and this is very natural in a case of large tumor mass of the greater curvature without gastric symptoms; see our Case 2.

The size of the tumor is a point of considerable diagnostic importance. In 6 cases the tumor was the size of a man's and in 5 of a child's head; in 3 cases they weighed from 10 to 12 pounds, projecting into the peritoneal cavity in 8 cases, and below the umbilicus in 9 cases. One case was operated on for tumor of the omentum, and another for ovarian cyst.

Although many cases run a short course, in a few instances gastric symptoms extended over a period of from two to five years. As previously pointed out, many cases run their course without symptoms until near the end, and frequently there are no symptoms referable to the stomach. The appetite and the gastric functions may continue to the end.

*Treatment.*—It is of interest to know that eleven cases have been operated on, with four deaths. In one case, that of Mintz', the patient recovered from a gastro-enterostomy, but died later from the tumor. A portion of the tumor was excised in two cases—Baldy and Dreger. In one case pus was evacuated from a gastric sarcoma with a fatal termination. In six cases the tumors were removed. In Capello's case, a woman 54 years old, a large cystic sarcoma of the stomach, the size of a man's head, mistaken for an ovarian cyst, was successfully re-

moved. The patient was in good health two years later. In a woman 52 years of age, Cantwell found a spindle cell sarcoma weighing 12 pounds, growing from the posterior wall of the stomach over a surface of five inches square. The tumor was successfully removed, but a secondary growth was discovered six months later. A successful operation for the removal of sarcoma of the stomach is credited to Billroth. In Dock's case, a man of 55 years, Nancrede successfully removed about one-third the long axis of the stomach and 2 cm. of the duodenum for a lympho-sarcoma, measuring 6 by 4 cm. The patient was well and had gained thirty pounds two months later. Hartley's case was even more remarkable. A woman 54 years of age, five years before coming under observation, vomited coffee-ground-like material, but had no other symptoms. There was no recurrence, and for four years she was in fair health, except for symptoms of indigestion which did not interfere with work. A year before applying for treatment she vomited coffee-ground-like material for five successive mornings. Pain in the back was a marked symptom. On physical examination a large, hard, elastic tumor was felt in the left lumbar and umbilical regions. At operation a large pedunculated tumor was removed from the posterior wall of the stomach. Schapf resected the entire stomach, the seat of a large lympho-sarcoma, in a woman, who gained flesh and was apparently well one year after operation.

**Conclusions.**—1. Gastric sarcoma is more common than is generally supposed, at least 61 cases being recorded. Careful routine microscopic examination of all gastric tumors met with at autopsy and operation will probably show a marked increase in the occurrence of these tumors. 2. The two sexes are affected in about equal proportions, as against five males to four females for carcinoma; 37.7 per cent. of the cases occurred below the fortieth year, and 11.44 per cent. (7 cases) below the twentieth year. 3. The pyloric end was involved in only 26.23 per cent. of the cases, as against 60 per cent. for carcinoma (Welch), and caused stenosis in only 8.19 per cent. of the entire number of cases. Diffuse growths occurred in 21.31 per cent., while the cardia was involved in only 4.9 per cent. The posterior wall and greater curvature are commonly involved. 4. Gastric sarcoma may reach a large size, that of a child's or man's head, and may project as large masses into the lumen of the stomach or into the peritoneal cavity, extending below the umbilicus—13.1 per cent. Such tumors have been mistaken for tumors of the spleen, omentum and ovaries, and may be pedunculated and readily removed. 5. Gastric sarcomata commonly start in the submucosa or muscularis and are less apt to ulcerate and cause hemorrhage than carcinomata. 6. All the histologic varieties of sarcoma have been found in the stomach. 7. While most of the cases in which the duration of the illness was mentioned ran an acute course, the average duration of life is probably from nine to ten months, while in one case it was three and in another five years. 8. Metastasis is not as frequent as in carcinoma, but may be widespread. The liver was invaded in only seven cases—11.47 per cent.—in striking contrast to gastric carcinoma, which, according to Welch's statistics, invaded this organ in 30 per cent. of cases. 9. There are no distinctive clinical symptoms or physical signs of sarcoma of the stomach, but a positive diagnosis has been made in three cases from microscopic examination of material obtained from the stomach. 10. In cases of large tumors connected with the stomach, especially

when they project to or below the umbilicus, a diagnosis of sarcoma of the stomach is warranted. A tumor of the stomach in an individual under 20 years of age is almost certainly sarcoma. In our series 37.7 per cent. of the cases were under 40, while in Osler's 150 cases of carcinoma of the stomach only 15.3 per cent. were under this age. 11. Operation should be as successful in sarcoma as in carcinoma of the stomach.

**The Fifth International Congress of Gynecology and Obstetrics.**—This congress will convene at Rome, September 15 to 21, 1902. Professor Mangiagalli will preside over the section of gynecology and Professor Morisani over the obstetric section. The committee of organization is composed of Professors Pasquali, of Rome, Pestalozzi, of Florence, and La Torre, of Rome, treasurer. The fee is 25 francs.

## The Organization of the Medical Profession.

### V.

#### Why Organization Has Failed in the Past.

(Continued from page 325.)

There is no wonder, if we recognize this as the ideal, that attempts at organization have failed in the past. Except in a few states, the county societies, what few there are, exist, to all intents and purposes, as independent organizations, each standing alone, struggling along without encouragement in its efforts, without help when it becomes weak, dying out or lying dormant for months or years, to be revived and struggle along again and again without help!

The state societies, as a rule, are independent organizations devoted to scientific and social purposes, and neglecting and ignoring the broad functions pertaining to a body representing the profession of the whole state. A study of the conditions existing in various parts of our country shows that in those states in which there are but few county societies the state society is weak in the number of its members and in influence; that its growth has been retarded because those who were trying to build it up did not realize that its growth and permanency rested on the county, or district society. They have been putting up the superstructure without the base, and then wondered why it crumbled down as fast as it was put up, and why new members came in barely fast enough to fill the places of those who were dropped for non-payment of dues.

#### Mutual Dependence of State and County Societies.

That there is an interdependence between the state and county societies has not been recognized. While there can not be a strong influential and prosperous state society without the support of active county organizations, the corollary is still more evident: There can not be strong active county societies without the aid and stimulus of a state society to encourage the weak, aid the struggling, and help to settle the petty troubles and disputes that are bound to occur in some of them. Those who are so anxious to have county societies permanently established should realize that simply planting a seed does not insure a full-grown flower; that it is usually necessary to water it and protect it from weeds. Organizing societies and then leaving them to die or live is simply traveling in a circle, going on a fool's errand. This is a fact that can not be stated too emphatically or too often.

#### Mutual Dependence of National and State Societies.

While these comments refer to societies in the individual state, they apply also to the state societies as a whole. These have been acting independently of each other, without any attempt at mutual help or interstate coöperation, which is so necessary if many of the objects of organization are to be met—and all this because there has been no close relationship between these and the AMERICAN MEDICAL ASSOCIATION. While mutual help and coöperation among the local societies of a state depend on a state society, so mutual help and coöperation among the state societies depend on a central or national society, in which they may federate and through which they can work.

As a majority of the state societies are independent of, and not closely related to, the county societies in the state, so until now the AMERICAN MEDICAL ASSOCIATION has been independent of, and without direct relation to, most of the state societies. It has for years been made up of men coming together according to the will of each individual. Nominally, membership in it depends on membership in an affiliated society; but for a long time it has been impossible to guard this right, since there has been no direct connection between it and the so-called affiliated societies, no method of verifying membership; as a result there are possibly hundreds who are not eligible to the membership in the AMERICAN MEDICAL ASSOCIATION which they now enjoy. As organized, the national association was ideal in its plan, the intention of its founders being to encourage the building up of local and state societies. Its legislative body was a representative one, made up of delegates elected by the lower societies—the county, district and state. But the tremendous growth of population and consequent increase in number of physicians and medical societies, without any change in the organic law of the association, had resulted in the legislative branch becoming fortuitous, unrepresentative and unwieldy, as well as too much engrossed in scientific and social work to have time to transact the important business that is the function of a great national body.

So all the way through, from top to bottom, there has been no system. Each state has been acting independently of all the others and no co-ordinate work or mutual help among the states has been attempted. Local societies have been started here and there, some to exist for a few weeks, some for a few months, and a very few to continue on with an ebb and flow of activity depending on the personal element that dominated them. The transactions of the AMERICAN MEDICAL ASSOCIATION and of the state societies are loaded down with resolutions favoring organization of county societies, but resolutions accomplish nothing. Spasmodic efforts have been made, but like spasmodic efforts in other things, they have resulted in failure. There is little wonder then that we hear it said that it is impossible to organize our profession. Those who are continually giving vent to these pessimistic views tell us that it can not be done, because it never has been done; that it has been tried year after year, and that we are no nearer to-day than we were fifty-seven years ago when the AMERICAN MEDICAL ASSOCIATION was started; and this seems to be true. In fact, there are several states in which the profession was better organized fifteen or twenty years ago than it is to-day. This in spite of the fact that so very many appreciate the need of organization and have been working in various ways to effect it.

The failure in the past has not only been due to not having a plan or system, but also to not having applied business principles to what little was attempted. We shall never have an organized profession as a result of volunteer efforts. There has been an immense amount of self-sacrificing work done in various parts of our country by a few individuals, but there is a limit to such efforts, and that limit has always been reached before anything more than a good beginning has been made. We can not expect even physicians to sacrifice their time, money and energy for the good of others beyond a certain point. There will never be an organized profession unless money is spent in its accomplishment and business principles applied as is done in other organizations.

## PARATYPHOID.

From time to time cases are being reported in the literature which appear like typical typhoid from the clinical standpoint, but in which the blood serum does not develop the power of agglutination of typhoid bacilli. Observations of this kind heretofore have been reported as proving that too much reliance can not be placed upon the diagnostic value of the agglutinative reaction, especially when the result is negative. But as has been pointed out before in these columns, in patients with the clinical symptoms of typhoid fever bacteriological examination of the blood has resulted in a few instances in cultures of bacilli differing in essential respects from the bacillus of typhoid fever. Such cases have been described by Gwyn, Kurth, Schottmüller; and others have recorded more or less similar observations. In these cases the serum reaction was negative in the case of typical typhoid bacilli, but positive with the bacilli cultivated from the blood.

Meltzer<sup>1</sup> presents an interesting summary of this subject. It seems that the bacilli isolated belong to the colon-typhoid group, but do not coagulate milk, ferment lactose or form indol at the same time as they do produce gas, ferment glucose and produce alkali. They therefore resemble very much the group of organisms to which are classed the meat poisoning bacilli, the hog cholera bacillus, Shiga's bacillus of dysentery, etc.; perhaps the most typical and generally representative organism of this group is midway between the colon group and the typhoid group, Gärtner's bacillus enteritidis. From observations on the agglutinative powers of appropriate serums upon the anomalous bacilli from typhoid-like cases it has been shown that while they are no doubt distinct from *B. enteritidis* of Gärtner, yet they have close relationships between themselves.

So far all the patients who have been studied with the results above referred to have recovered. In addition to the general symptoms of typhoid intestinal hemorrhages, late osteomyelitic foci have been noted, but nothing is known of the pathological anatomy of the disease. It would indeed be very interesting to learn what the changes in the intestines may be in these cases, and also whether the same microscopic changes occur in the lymphadenoid tissue of the intestines, mesentery and spleen as in typical typhoid fever. Meltzer proposes the term paratyphoid as the most suitable name for the dis-

case and paratyphoid bacilli as the most appropriate designation for the organisms. He argues with much plausibility, that the persistent absence of the serum reaction with typhoid bacilli in a supposed case of typhoid fever means that the disease is caused by a paratyphoid bacillus. In the Hamburg epidemic of typhoid fever investigated by Schottmüller (sixty-eight cases) six cases proved to be paratyphoid. In Bremen, Kurth found five paratyphoid cases in an epidemic of sixty-two cases of typhoid fever. Here are two typhoid epidemics yielding eight per cent. of paratyphoid. This would be rather a higher percentage than usual of negative serum reactions in typhoid fever when compared with statistics from hospitals and boards of health. Meltzer is inclined to believe, however, that in many cases of paratyphoid there may have been a mixed infection with typhoid bacilli sufficient to give rise, in the serum of the patient, to substances agglutinating typhoid bacilli, and such cases would be classed as typhoid fever. He supposes that the intestines may contain in the first place large numbers of virulent paratyphoid bacilli and a small number of typhoid bacilli of only moderate virulence; as the paratyphoid bacilli cause necrosis of the epithelium of the intestine and enter the circulation symptoms entirely like those of typhoid fever make their appearance. At the same time a small number of typhoid bacilli pass into the circulation and cause specific agglutinins so that the blood of the patient causes, let us say, a reaction in a dilution of one in twenty. Such a case would be diagnosed as typhoid fever. In reality, however, it would be an example of paratyphoid infection. If the blood, feces or urine of such patients were examined carefully bacteriologically, the paratyphoid organism might be isolated and the serum of the patient might be found to have much stronger agglutinating power upon this bacillus than upon the typhoid bacillus. Durham has done some interesting and suggestive work in this line. Meltzer suggests, therefore, that the blood of patients with supposed typhoid fever, but giving the serum reaction only in small dilutions or not at all, should be tested also with paratyphoid bacilli. In this way a clue to the nature of the disease might be obtained and this would also stimulate to careful bacteriological studies which should be made in all doubtful cases, and which finally would place the diagnosis upon an absolutely correct etiological basis.

These developments in the knowledge concerning the disease or group of diseases known as typhoid fever are attributable to the careful application to clinical medicine of the methods of the bacteriological laboratory. The results show that an etiological diagnosis, based upon strictly scientific methods, always comes nearer to the true nature of diseases than the ordinary diagnosis, which is based purely upon the clinical symptoms, ever can hope to do. But of what value is all this to the physician and to the patient? Perhaps of but little apparent, immediate practical value. To the general practitioner, Meltzer's summary indicates the direction

1. N. Y. Med. Monatschrift, January. N. Y. Med. Jour., 1902, January, 138-142. See also p. 425.

in which development is going; that the application of modern methods to the study of well-known diseases is about to separate distinct etiological forms hitherto classed as one disease. And as to the patient, it should be remembered that a diagnosis which rests upon the basis of the specific etiology is the essential step towards establishing the true indication for treatment, namely, the *Indicatio causalis*. In the case of typhoid and paratyphoid specific treatment is not yet available, but if it ever comes it would not be surprising to learn that the curative serums show the same intimate relationships to the different bacilli as do the agglutinins; that typhoid serum is not curative in paratyphoid, and vice versa. And should this prove true the best chances of proper treatment would rest upon correct diagnosis. In any event it may be found, as we learn more about paratyphoid, that the patients are better treated according to methods different from those now applied to the treatment of typhoid fever, and that paratyphoid is a law unto itself in some respects.

#### DIABETES AS A MANIFOLD DISEASE.

Vital statistics in recent years show a distinct increase in the death-rate from diabetes mellitus. Statistics showed that the average death-rate in this country was considerably below that of other countries, but it is now approaching the foreign mortality figures. As a rule, this increase in the mortality is not considered significant of an actual increase in the frequency of the disease, but as a result of better methods of diagnosis, fewer cases of diabetes escaping recognition. The terminal stage of diabetes in the past has not infrequently masqueraded under the cloak of tuberculosis, or, that common sequela of continued glycosuria, nephritis.

The most prominent clinical feature of diabetes is the manifold differences that exist between different cases of the disease, so that the conclusion is reached that these distinct types of the disease must have dissimilar pathological bases. This thought is confirmed by many clinicians. Lauder Brunton<sup>1</sup> says that all the forms of albuminuria used to be called "Bright's disease," and all glycosuria "diabetes." In reality there are many different forms of both affections, some of comparatively little importance, while others are malignant in character. The English clinician goes so far as to add that "for very stout people one begins to think what would become of them if they had not some sort of safety valve like glycosuria to get rid of the excess of carbohydrates they took."

It has always been debatable whether mild forms of diabetes ever progressed so as to become severe forms. In most fatal cases there has been no hesitation as to the severity of the affection from the earliest moment of its recognition as true diabetes. Naunyn, who is probably one of the best authorities in Europe on dia-

betes, says:<sup>2</sup> "Admittedly light forms of diabetes remain always benignant." He acknowledges that apparently mild types of diabetes may grow worse, but he is of the opinion that the transfer of any special case from the category of mild to that of severe diabetes has not been observed with sufficient definiteness to make an absolute opinion in the matter possible. It is certain that diabetes mellitus in persons of obese habit or of a gouty or arthritic diathesis may lead to glycosuria of large amount without seriously endangering the health of the patient or shortening life if certain dietary regulations are not too badly infringed. With regard to the pathological basis of diabetes there are good reasons to believe that change in the nervous system, in the liver, or in the pancreas may each represent the underlying causative lesion of the disease.

To this manifold pathogenesis a new and striking feature has recently been added. Dr. F. Blum,<sup>3</sup> while testing the effects of suprarenal extract injections upon animals, found that glycosuria occurred in 22 out of 25 animals experimented on. Croftan seems to have made the same discovery independently and simultaneously. He says:<sup>4</sup> "The injection of suprarenal extract can cause the excretion of dextrose (in the urine) provided the quantity injected is sufficiently large." He adds that the reason why more must be given to one animal than to another to produce approximately the same excretion remains to be determined.

This new feature of the pathology of diabetes, far from being a source of confusion or discouragement in an already involved subject, is a confirmation of the accepted views of clinical observers as to the manifold nature of the disease. In diabetes, as in so many other affections, pathology is gradually coming to supply, though dilatorily, the scientific basis for the truth of the conclusions of clinical experience. The present situation should be a source of renewed encouragement to labor in the recently almost neglected field of actual bedside observation of disease as the surest source of practical medical knowledge.

#### THE NEW YORK OSTEOPATHY BILL.

The interference with personal liberty is the usual argument against any proposed new sanitary or moral regulation. It is the pet plea of the quack as well as of the doggerly keeper. The unthinking crowd are easily caught by its specious sound, and even those who claim culture and enlightenment are sometimes found using it in advocacy of measures that without this appeal to their prejudice they would repudiate. The word liberty has become a sort of national-fetish and is used most by those who have the least idea of its true significance or those who from interested motives find it convenient for them to do so. There is no civil liberty without restrictions; otherwise we would have only anarchy.

2. Nothnagel, *Specielle Pathologie und Therapie*, vol. vii. (1) Naunyn: "Der Diabetes Mellitus," p. 350.

3. *Deutsche Archiv f. Klin. Medicin*, Oct. 30, 1901.

4. *American Medicine*, Jan. 18, 1902.

1. "Disorders of Assimilation and Digestion," p. 51, Macmillan & Co., New York, 1901.

These points are well brought out by Dr. Floyd M. Crandall in a recent article<sup>1</sup> in which he especially reviews the arguments adduced by the osteopaths and their advocates in their attempt to have their methods legalized in New York. He shows by reasoning that ought to be conclusive to anyone not blinded to all facts, that if anything requires special training it is the practice of medicine, and this not for the advantages of existing members of the profession, but for protection and welfare of the public. That the public does not recognize this as it should is one of the unfortunate facts of human weakness, and that the self-interested outcry of violated personal liberty by quacks and their advocates finds such ready acceptance is another.

Much of Dr. Crandall's paper is a reply to the allegations of this kind by a noted writer whose good sense seems to have deserted him when he came to discuss these matters. There are others like him, and were it not for these men of presumably more than ordinary mental ability being thus misled by taking delusive catchwords, it would seem needless to argue that the practice of medicine should be restricted to those qualified by special training. It ought to be a self-evident truth to every man of sense; unfortunately there are many who would resent any implication on their intelligence and yet who not only patronize quackery, but apparently want it undiluted with any possible admixture of genuine medical science. It is osteopathy pure and simple that these people want in New York and elsewhere; the requirement of the passage of the state examinations and demonstration of general medical qualifications by the osteopath would rob it of its virtue by abridging the personal liberty of the citizen to employ an ignoramus to care for his health. New York has, we believe, gone further in the recognition of the principle of the necessary restriction of personal liberty than most other communities, by making suicide a felony. Why should it repudiate its precedents by nullifying much more obviously rational restrictions on its statute books?<sup>2</sup>

#### THE HYGIENE OF THE RAILROAD CAR.

In a discussion of the hygiene of tuberculosis,<sup>3</sup> Frank W. Wright concludes with a consideration of the duty of common carriers. What he says as related to tuberculosis, might equally well be applied to infectious diseases in general, and especially to those which are commonly known as contagious.

The railroad car, which is inhabited for hours or days by numbers of individuals, and going from one place to another at longer or shorter distances, may readily be a means of spreading infectious diseases from one person to others and from one locality to more or less remote ones. In the ordinary sleeping car, which is supposed to furnish the traveler with every possible com-

fort, many conditions could not be better for collecting and harboring infectious germs if they had been planned expressly for the purpose. The upholstery, which might be of leather, is usually plush, and the woodwork is often made to furnish as many places for the collection of dust as possible.

From a hygienic point of view, the upholstery and hangings should be as limited as possible, and of such a nature as can be readily renovated; the woodwork should be smooth and without decorations or sharp angles for the collection of dust; provision should be made for ventilation without the necessity of a cloud of smoke and dust being blown through the car; and the dust which collects should either be allowed to remain undisturbed until the car is empty of passengers, or removed with a moist cloth, instead of being periodically distributed through the car by the ubiquitous duster of the porter. Cuspidors containing an antiseptic solution should be provided. At the end of each trip, the car should be carefully cleaned and disinfected by men who understand the practical use of disinfectants. Drinking utensils should be included in the general disinfection, as should also toilet articles for common use, such as hair combs, brushes, etc. Closets should be carefully cleansed and washed with reliable antiseptic solutions. Each railroad should have an official who is a practical hygienist, who would be responsible for the suggestion and execution of all such details as would naturally occur to such a person.

So long as railroad companies vie with each other in making their cars as luxurious and as gaudy as possible, without regard to after-effects on their patrons, just so long will railroad travel be accompanied with danger from infectious diseases.

#### MEDICAL LIBRARIES FOR MILITARY STATIONS.

An editorial in one of our contemporaries<sup>1</sup> in India calls attention to the fact that in many respects the regulations for the Medical Department of the United States Army do not differ materially from those in the Royal Army Medical Corps of India. A provision which is made for the Medical Department of the U. S. Army which is lacking in the Royal Army Corps, namely, a medical library and the leading medical journals for each military station, is especially noted. The writer is surprised that the Indian medical authorities have not thought of this. If the medical men in the army are to keep abreast of the advances in medicine, such a provision should certainly be made, and our authorities are to be congratulated that they have not overlooked this important matter.

#### CHARLATANISM AND CHEEK.

A Colorado correspondent has favored us with a circular letter sent out by an "osteopathic college" in Denver which for brazen effrontery caps the climax. The physicians of Colorado and adjoining states, we are told, are

1. New York Medical Journal, Jan. 25, p. 148.

2. Since the preceding was written, we have learned that the bill has been killed in committee.

3. Yale Medical Journal, viii, 1902, 201-207.

1. Indian Med. Gazette, xxxvi, 1901, 461.

receiving these letters and are accepting (?) the gracious offer with alacrity. It is not often that physicians have the opportunity of learning the theory and art of massage for the small sum of \$200. Possibly the "individual attainments," plus the financial side, will make it possible for most of them to shorten the time "left to our judgment," with the right kind of persuasion. For the benefit of those who may not have been favored with a copy of the original, we reproduce the letter, grammar and all:

To Physicians: Having several medical graduates to apply for a short course in osteopathy, we are considering the starting of a class February 1st, for their benefit, and will do so if a sufficient number will enter for it. We will accept medical diploma for the subjects usually taught in medical colleges, and give a short review of special osteopathic features in physiology, together with regular lessons in osteopathic theory, principles and practice, as well as practical clinical work. The price will be made \$200, and while nominally requiring ten months, this time may be shortened if the individual attainments of the applicant justify it. This, however, must be left to our judgment, as determined by our examinations of the applicant. Our secretary will be pleased to call on you if you will signify your willingness to consider the matter with him.

#### PROTECTIVE INOCULATION AGAINST TYPHOID FEVER.

The testimony of British military surgeons in South Africa continues favorable to the usefulness of inoculation with sterile cultures of the typhoid bacillus in reducing the mortality from typhoid fever and in diminishing the severity of the disease. According to the most recent report, as made by Major C. Birt,<sup>1</sup> there occurred at Harrismith, between September, 1900, and September, 1901, 1210 cases of typhoid fever, of which 947 were among uninoculated and 263 among inoculated individuals. Of the uninoculated, 135 died, or 14.25 per cent.; of the inoculated, 18 or 6.8 per cent. The average duration of the pyrexia was 28 days in 317 cases in uninoculated persons, and 15 days in 151 cases in inoculated persons, the average maximum temperature in the former being 103.7, in the latter 102.9. The percentage of cases among the uninoculated in which relapse took place was 24, as against 6 among the inoculated. Constipation was present in 19 per cent. of uninoculated cases, and in 33 per cent. of inoculated cases. In the cases with diarrhea there was an average of 4.4 daily evacuations among the former, and of 2.6 among the latter. In all the fatal cases among inoculated persons, eight months or more had elapsed since the protective vaccination. That immunity to typhoid fever is not readily established in some persons is shown by citation of the case of an uninoculated man who, four months following a mild attack of the disease, died as a result of a virulent attack. The statistics that have thus far been presented go far to sustain belief in the efficacy of protective inoculation against typhoid fever as practiced by the English military surgeons, and they more than justify continuance of the practice.

#### POLITICAL INFLUENCE OF PHYSICIANS.

A newspaper editorially remarks that "those who have the making and executing of the laws, whether they be called politicians or statesmen, are prone, as a rule, to underestimate the value of the good opinion and the

influence of physicians."<sup>1</sup> It is refreshing to see such a truth announced from such a quarter; the newspapers themselves have not, as a rule, sufficiently appreciated the possible influence of the medical profession. The paper goes on to say that the physician comes in closer touch with the people than the representative of any other profession, and that the "doctors could insure the success of any candidate for any elective office in the state if only any considerable percentage of them would undertake it. . . . A candidate for a state office could very well afford to say that in anything like a close contest, if he had all the physicians with him, he might not care what class supported his opponent. If the resolutions passed by county medical societies are not heeded by legislatures and executives they are antagonizing a very powerful element." The editorial further says that because physicians do not habitually dabble in politics or constantly seek for office, their influence is the more potent when once it is thoroughly exerted. This we believe is a truth and if we act with due wisdom, showing by our conduct that when we do act our motive is the public welfare as well as our own interests, we can be invincible. There are enough physicians in every state to control medical legislation if they will only act together. Thackeray says that any woman without an actual hump can marry any man she pleases; man's safety is that women are like the beasts of the field; they do not know their own strength. The same might be said of the physicians of the country; they have not appreciated their own power. If quackery thrives and gains recognition and privilege under the law it is the fault of an inactive and unorganized medical profession.

#### PRUDERY OR POLITICS.

The warden of the Cook County Hospital, a layman who has nearly absolute power in that institution, not long since prohibited bedside clinics, and has now put his veto upon all public gynecologic clinics whatever. The superintendent of the corresponding institution in Milwaukee, Wis., has, it is reported, followed his example and now prohibits clinics or the attendance of medical students at operations on women where any exposure is necessary. This cuts off a very important part of the clinical instruction, and ought certainly to have good reasons to justify it. So far as we have seen, the excuses are that it shocks the sensibilities of the warden, and especially that some medical students have been discourteous in their behavior. As regards the first point it does not probably occur to the official that in this he is setting himself up as a critic of all who have preceded him, and of all the physicians in charge who have not, as a class, been accused by others of not possessing gentlemanly instincts, as is implied by the course he adopts. There need not be anything degrading or necessarily offensive to a modest patient in a gynecologic clinic, and we believe that it is the practice, so far as possible, to respect her feelings and wishes. Foreign observers have remarked on the contrast in this regard between methods here and abroad and have criticised what seemed to them the superfluous delicacy of American surgeons. This answers also the second alleged excuse; if there was improper behavior on the part

1. British Medical Journal, Jan. 11, 1902, p. 75.

1. The Utica (N. Y.) Press, January 22.

of students it should have been checked and the guilty individuals excluded, not necessarily the whole class. It is not necessary to burn a house down to roast a pig. If any of the instructors or surgeons fail to cultivate a proper morale at their clinics they could be admonished, or even excluded, should that extreme measure be required. If they have not, the action taken is a slander by implication. It reflects also upon the discipline maintained and does not suggest the highest type of executive ability on the warden's part. If a man with absolute power in such an institution can not insure proper conduct except by destroying one of its useful functions, it might be well to have someone better qualified take his place. There are those who could permit gynecologic clinics without the suspicion of impropriety. On the whole, the transaction suggests an unacknowledged motive; it appears to be to a large extent a gallery play of a politician to catch the sentimental public. It will fulfill its purpose and then gradually the old order will be resumed. Politically managed hospitals can only reform spasmodically, and even such pseudo reforms will follow the same rule. A judicious restriction of free clinics, not only gynecologic, but generally in all departments of surgery and medicine, would be undoubtedly a good thing for the medical profession, and perhaps not altogether a bad one for the public. Any such wholesale cutting off, however, of the means of instruction in an important specialty is condemnable in every sense of the word.

## Medical News.

### CALIFORNIA.

**Banquet Dr. Fenger.**—A number of Los Angeles physicians gave an informal banquet at the Hotel Green, Pasadena, January 26, in honor of Dr. Christian Fenger, who has been visiting in Southern California. Dr. Norman Bridge was toastmaster, and among the speakers were Drs. J. H. McBride, Walter Lindley, George E. Abbott, F. F. Rowland, J. M. Radabaugh and F. B. Bullard.

**Personal.**—Dr. Hiram A. Hess has been elected surgeon-in-charge of the Pacific Hospital, San Francisco.—Dr. William W. Roblee and family, Riverside, have started on a trip to Europe.—Dr. William C. Hopper has been appointed resident physician of St. Mary's Hospital, San Francisco, vice Dr. Joseph W. Henry, resigned.—Dr. George H. Evans, San Francisco, secretary California State Medical Society, is in New York doing post-graduate work.

### DISTRICT OF COLUMBIA.

**Central Dispensary and Emergency Hospital.**—At the meeting of the attending staff held February 1, the appointment of Dr. Francis J. Doyle to succeed Dr. Kuhn was approved. Dr. Kuhn has passed a competitive examination, and has been appointed resident physician of the Columbia Hospital.

**Health of the District.**—The report of the health officer for the week ended January 25 shows the total number of deaths to have been 122, of which 64 were white and 58 colored. At the close of the week there were 42 cases of diphtheria, 34 cases of scarlet fever and 2 cases of smallpox under treatment; 101 births were recorded.

**Eastern Dispensary.**—The quarterly report of the Eastern Dispensary shows the institution is growing rapidly and doing excellent work. The report shows that of 423 applicants for free treatment 101 were refused on the ground of being unworthy and impostors on medical charity. Twenty-eight operations were performed, 1504 prescriptions compounded and 255 emergency cases treated.

**Columbian University Hospital.**—The Commissioners of the District have refused to grant free water to the Columbian University Hospital. The extra expense of water will be a great hardship to the university as it is a self-supporting institution for the clinical instruction of medical students and receives no appropriation from Congress. Under the present law institutions receiving support through Congressional appropriations are granted free water.

**To Care for the Sick Poor.**—The Associated Charities of the District recently held a conference looking towards the betterment of the sick poor, the purpose being to assist the worthy poor who are needy of medical treatment and yet shrink from the painful notoriety now given in cases of application for charity medical treatment. The Secretary of the Charities discussed the methods and ways and means with Dr. Burnett, Health Officer Woodward, Drs. G. M. Kober and H. L. E. Johnson; Messrs. J. W. Boardman, president of the Emergency Hospital, Ex-District Commissioner White and Ex-Secretary of State Foster. Resolutions covering the subject were adopted to be presented to the Medical Association of the District for approval.

### GEORGIA.

**Smallpox** is prevalent among the negroes in Elbert County.

**School Inspection.**—The schools and school-children of Atlanta are to be inspected systematically by a corps of 36 physicians which serves without compensation.

**Counterfeiter a Physician.**—In the United States Court at Rome, Dr. Russell D. Stallings, Clem, Carroll County, was recently sentenced to serve five years in the penitentiary and to pay a fine of \$500 for counterfeiting and passing spurious coin.

**Marine-Hospital for Savannah.**—Senator Clay has introduced a bill providing for a marine-hospital for Savannah. The importance of Savannah as a shipping port and the fact that there is no marine-hospital nearer than Wilmington, N. C., are the chief arguments advanced.

**Personal.**—Dr. William C. Jarnagin has been re-elected president, and Dr. Everard H. Richardson, secretary of the Atlanta Board of Health.—Dr. Ralph Comer, Dyson, has located in Tignall.—Dr. Howard J. Williams has been chosen to succeed the late Dr. William F. Holt on the medical board of the Macon Hospital.

### ILLINOIS.

**Hospital Consecrated.**—The new St. Francis Hospital, Peoria, was consecrated with imposing ceremony, January 29. The building was recently completed at a cost of \$120,000.

**The Irreverent Press.**—In a recent issue of the Chicago *Record-Herald*, the new Hospital for the Incurable Insane, at Bartonville, is editorially dubbed a "Home for Incurable Politicians."

**Personal.**—Dr. J. Harvey Banks, Atlanta, has moved to Lincoln.—Dr. John W. Turner, Homer, has disposed of his practice to Dr. Bashaw, Berlin.—Dr. D. J. Evans, Chicago, has been appointed assistant to Dr. F. G. Hall, of the Burlington Voluntary Relief, Galesburg, vice Dr. Charles Hamilton, resigned.—Dr. John P. Riggs, Roseville, has moved to Plano.—Dr. William R. Kincaid, Elkhart, has moved to Denver, Colo., and is succeeded by Dr. Joseph T. Woodward.—Dr. Thomas J. Stafford, Stockton, has been appointed an auxiliary member of the State Board of Charities.—Dr. O. H. Irwin, Sheldon, has sold his practice to Dr. Ethan Allen.—Dr. L. St. C. Whitley, Springfield, has returned from a trip of several months through Europe and South Africa.—Dr. Charles W. Rook, Quincy, has returned to his old home near Bowen, Hancock County.—Dr. John C. Owens, Plainfield, recently fractured his hip in a runaway accident, near Aurora.—Dr. Emmett F. Enos, chief of staff at the Illinois Eastern Hospital for the Insane, Kankakee, has resigned.—Dr. Burdette E. Le Due, Plano, has retired from practice on account of ill-health.—Dr. Simeon M. Robertson, Gresham, has moved to Mount Vernon.—Dr. Roy S. Blackburn, Ray, has located in Lowpoint.—Dr. Benjamin D. Baird, Williamsfield, has opened an office in Galesburg.—Dr. Everett H. Butternell, Ottawa, has gone to Baltimore for post-graduate study.—Dr. J. M. Mitchell has located in Pontiac.—Dr. Frederick C. Taylor, Florid, has moved to Granville.—Dr. Julian W. Zinn, Graymount, has located in Joliet.

### Chicago.

**Swedish Hospital.**—Plans have been prepared for a hospital to be built for the Swedish Mission Association in Bowmanville or Lake View, to cost about \$50,000.

**Proposed College for Women.**—It is incorrectly announced in the daily press that Dr. Eliza H. Root and three Evanston women are heading a movement to organize a medical school for women. The statement is not true.

**Co-Education at Rush.**—Despite the protests and opposition of certain members of the faculty, a resolution was passed by that body January 24, recommending the admission of women to all branches of the Medical Department of the University of Chicago.

**No Quarantine.**—Although smallpox is prevalent in Iowa, Indiana and Wisconsin, the Health Commissioner will not quarantine against these states, but will institute an inspection system to protect Chicago from the disease. There are at present 22 patients in the Isolation Hospital.

**The City's Deaths.**—The deaths for the week ended February 1 numbered 517, equivalent to an annual death-rate of 14.80 per 1000. This was an increase of 37 deaths over those of the week before—chiefly from acute intestinal, heart and nervous diseases and from consumption, pneumonia and scarlet fever. Influenza is still very prevalent and, although of a mild type in itself, is mischievously and often fatally complicated with many other maladies.

**Combine Against Smallpox.**—An effort in preventive medicine on a scale of considerable magnitude was inaugurated last week by the Health Department. Its field is an area of some 600,000 square miles of territory in the ten states of which Illinois is the southern center and the remotest boundaries of which are within a few hours' railway travel from Chicago. Between Dec. 28, 1900, and Jan. 24, 1901, there were only 1070 smallpox cases reported in this territory, while during the similar period ended Jan. 24, 1902, there were 10,820 cases reported—an increase of 911 per cent. At a conference between the representatives of the chief railroads centering in Chicago and the Health Department, ready assent was given to the plan proposed which contemplates wholesale vaccination and revaccination in every infected locality; the provision and maintenance of suitable isolation hospitals where necessary; thorough disinfection of smallpox premises and belongings; strict inspection of all persons offering to travel from infected localities and refusal to carry those who do not comply with the requirements. Special attention will be paid to the condition of employees in manufacturing establishments—particularly those of textile fabrics—and the railways will see the example by still more rigorously making recent vaccination a condition of further employment. Competent vaccinators and supplies of pure, tested vaccine lymph will be furnished gratis in all proper cases. The work along each railway line will be under the direct charge of the medical director or chief surgeon of the company and a central office will be maintained in the city for the receipt of reports, requisitions, etc., from those engaged in the campaign. Dr. Reynolds has volunteered to take charge of the central office.

#### MARYLAND.

**Hospital for Naval Academy.**—The Secretary of the Navy has asked for an additional \$200,000 from Congress for a hospital for naval cadets at Annapolis. Singular to say, this was overlooked in the plan for the new naval academy.

**The ladies of the Children's Hospital of the Home of the Friendless** will have a concert by the famous Faderewski on February 28 for the benefit of the hospital, which is one of the most completely appointed child's hospitals in the country.

**Reception at Johns Hopkins.**—A reception was given the students and faculty of Johns Hopkins University by the Medical Department January 25, in the assembly room at the Johns Hopkins Hospital. There was a large gathering, the object being to promote acquaintance.

**The deaths** for week ending February 1 were 215, pneumonia causing 34, consumption 21, heart disease 19, Bright's disease 13, cancer 8, diphtheria and influenza each 4, typhoid fever 2. A number of cases of diphtheria, scarlet fever, whooping cough and variola are reported over the city.

**Personal.**—Assistant Surgeons George E. Marchand, of Annapolis, and J. H. Ullrich, of Baltimore, have been promoted to be full surgeons in the United States Coast Survey Service. —Dr. Claude L. Holland, resident physician of Franklin Square Hospital, Baltimore, has resigned and will go into practice in Morgantown, W. Va. —Dr. J. E. Dwinelle, Baltimore, was knocked down by a coaster, receiving a severe scalp wound.

**Quarantine Physician's Report.**—The report of the quarantine physician recommends the erection of a crematory for

the burning of the bodies of those dying of smallpox and yellow fever. Thirty-nine patients were treated during 1901, 21 being smallpox cases, and 2 being scarlet fever. The expenditures were \$17,961 and the fees and fines from 1007 vessels inspected were \$17,805, the station being virtually self-supporting.

**Neglect of Negro Insane.**—In the report of the Lunacy Commission to the Governor, Dr. John Morris, president, calls attention to the neglect of the negro insane in Maryland. Insanity is rapidly increasing among the negro population as the result of the idleness, lawlessness, debauchery, drunkenness, poverty, etc., so prevalent among them. Maryland is far behind her sister states of the South in the care of such cases, notably Virginia, North Carolina, Georgia and Alabama.

**Shepherd and Enoch Pratt Hospital** for mental and nervous diseases, Baltimore, shows 109 men and 100 women treated during the year. Sixteen died and 101 were discharged. Of the discharged 27 were recovered; 19 much improved; 18 improved, 31 unimproved, and 6 were hysterics, inebriate or drug users. Only curable cases were admitted in 1901. A building has been erected for recreation. Mr. Seymour Ludlam an advanced student in the Johns Hopkins School, and Dr. Glanville G. Rusk, have been added to the hospital staff.

#### MASSACHUSETTS.

**Memorial Hospital, Worcester.**—At the annual meeting of the trustees of the hospital it was announced that Mrs. Georgie Crompton Wood had given \$20,000 for an operating room.

**East Boston Vaccinated.**—A corps of 125 vaccine physicians descended on East Boston, January 26, and made a house-to-house visitation, inspecting or vaccinating every person in every house. More than 15,000 were vaccinated.

**Dr. Adolf Meyer**, instructor at Clark University, and head pathologist at the Massachusetts Insane Hospital, at Lake Quinsigamond, has accepted the position of head pathologist of the New York Pathological Institute, in New York City, to succeed Dr. Ira Van Giesen, resigned.

**For Harvard Medical School.**—The president of the University has announced the offer of John D. Rockefeller to give \$1,000,000 toward the three buildings needed for the medical department, provided that \$500,000 is subscribed for the purchase of land.—By the will of Miss Ellen O. Proctor, of Brookline, \$50,000 is bequeathed to the school for the study of chronic diseases.

#### MINNESOTA.

**St. Barnabas Hospital**, Minneapolis, is to erect a three-story building for a nurses' home, to cost \$25,000.

**Addition to Anoka Hospital.**—A \$30,000 addition is to be built at the Anoka State Asylum, and also a cottage to cost \$40,000.

**Indian Hospital Burned.**—The Agency Hospital connected with St. Columbs Hospital Mission at the White Earth Agency, was entirely destroyed by fire January 19. Fortunately no patients were in the hospital.

**Enforcing Vaccination Law.**—Three residents of St. Paul who had refused to allow vaccinators of the city health department to vaccinate them after they had been exposed to smallpox, each paid a fine of \$10 for their recalcitrance.

**Anatomical Laboratory on Fire.**—A fire in the anatomical laboratory of the University of Minnesota, Minn., January 25, caused a loss of \$10,000. By heroic work on the part of the students, the valuable libraries of Professors Erdman and Reed were saved, but about 20 cadavers and a valuable collection of skulls were burned.

#### MISSOURI.

**Golden Wedding.**—Dr. and Mrs. Edward J. Atkinson, Nevada, celebrated their golden wedding, February 3.

**Physicians Feast.**—The annual banquet of the City Hospital Alumni Association, St. Louis, was held at Faust's at the conclusion of the regular monthly meeting.

**Marine Hospital a Ruin.**—It is estimated that it will require \$60,000 to put the Marine Hospital, St. Louis, into habitable shape. It was erected about fifty years ago and has had little in the way of repairs done since that time.

**Dr. Gregory's Semi-centennial.**—Dr. Elisha H. Gregory, St. Louis, professor of principles and practice of surgery and clinical surgery in Washington University, ended his fiftieth year of lectures at that institution, January 17. At the close of his lecture he was given a large bouquet of roses and violets,

and eulogistic addresses were made by the chancellor and members of the faculty.

**Medical Association of Missouri.**—The Committee on Scientific Communication of this Society, consisting of Drs. Blencowe E. Fryer, 520 East 9th St., Kansas City; J. H. Duncan, Century Building, St. Louis, and M. B. Overholzer, Harrisonville, announces that it is ready to receive titles of papers to be read at the coming meeting to be held in St. Joseph, May 20, 21 and 22. The Committee will classify subjects or topics and requests that each author prepare a synopsis of his paper, not to exceed 100 words, and that the title and synopsis be in the Committee's hands not later than April 1.

#### NEW YORK.

**For Medical Research.**—Charles T. Ham has given \$5000 to the Rochester Academy of Medicine to be used to further medical research.

**Utica Isolation Hospital.**—A bill has been introduced appropriating \$5000 for the erection of a hospital for contagious diseases in Utica.

**Gifts to Hospitals.**—Maternity Hospital, Niagara Falls, has received \$4000 from the relatives of Benjamin F. Thurston. —Schenectady Hospital has benefited to the extent of nearly \$2000 by Hospital Sunday. —William C. Whitney has presented \$6000 to the Mineola Hospital.

**The Lunacy Bill.**—According to present appearances, Governor Odell's bill to abolish the lay boards of managers of the State hospitals will become a law. It passed the Senate by a vote of 97 to 45, and is expected to pass the House despite the strong opposition it has aroused.

#### New York City.

**Dr. Joseph S. Carreau**, who died in this city on January 7, is said to have left an estate worth nearly \$100,000. There are many relatives who claim a share in the estate, and so far it has been impossible to find any will.

**Loomis Hospital for Consumptives.**—A woman's guild, comprising 200 members, has just been organized. Its special work will be in aid of the Loomis Hospital for Consumptives in New York City and for the charitable department of the Loomis Sanitarium at Liberty.

**New Site for Woman's Hospital.**—The present site of the Woman's Hospital has been sold to the New York Central Railroad for \$450,000. It is probable that a new site will be purchased, consisting of 14 lots on the east side of Amsterdam Avenue between 109th and 110th streets.

**Dr. Manley Vindicated.**—In part IX of the N. Y. Supreme Court, before Judge McLean, an action was brought by Selina Schneider against Dr. Manley for alleged malpractice in the unnecessary removal of a joint of the thumb. After a two days' trial, the jury, after a five minutes' deliberation, brought in a unanimous verdict for the defendant.

**Tuberculosis Pavilion Opened.**—During the past week the city authorities have opened a tuberculosis pavilion in connection with the Metropolitan Hospital on Blackwell's Island. It contains 120 beds, and it is hoped that there will be a sufficient appropriation forthcoming to allow of building a long, open porch, where, protected from the wind, the patients may get the benefit of open-air treatment. Special diet will be provided, and it is intended to make use of forced alimentation.

**Trustees for the City Hospitals.**—On February 1, Bellevue Hospital and the other hospitals under the control of the city passed out of the jurisdiction of the Commissioner of Charities and under the charge of seven trustees, who serve without salary, and are not subject to the Mayor's general power of removal. They will have the full management of the hospitals, and will appoint and remove physicians, superintendents, nurses and attendants. It is hoped by this system to take these hospitals out of the domain of politics.

**Smallpox.**—According to Dr. Alonzo Blanvelt, Chief Inspector Division of Contagious Diseases, there have been between 60 and 70 cases of smallpox in the city during the past month. Mr. William C. Fosdick, of Flushing, Borough of Queens, has instituted habeas corpus proceedings to compel the return of his four-year-old daughter from the Isolation Hospital on North Brother Island. She was forcibly removed from her home, a diagnosis of smallpox having been made by one of the physicians of the Health Department. Four other physicians certified that the child was only suffering from chicken-pox, and she was removed. It is claimed, in direct

opposition to orders from a Supreme Court. A girl who was ill with smallpox in a tent on the grounds of the Smith Infirmary was nearly chilled to death in a storm, which put out the fire in the stove, knocked down the smoke-pipe, and nearly blew down the tent. The two nurses finding it impossible to keep the child warm by bedclothing, jumped into the patient's bed and kept her warm until morning.

**Dynamite Causes Havoc.**—An accidental fire in a small powder house in which was stored a quantity of dynamite for use in the subway tunnel, caused a very severe explosion at Park avenue and Forty-first street. The Manhattan Eye and Ear Hospital, which was close by the spot where the explosion occurred, was badly shaken and damaged, so that several days will be required to put it in repair. There were 63 patients in the hospital, and most of them, together with the nurses and physicians, were more or less injured by flying glass. Dr. T. Passmore Berens was hurt, and among the patients was a boy who was convalescing from an operation for abscess of the brain. No one of the many in the building at the time was seriously hurt, but the entire front of the building was wrecked and nearly every room made untenable. About sixty windows were broken in the Hospital for Ruptured and Crippled, situated two or three blocks distant from the explosion, and the children were thrown into a panic. While six surgeons, in an ambulance from the Roosevelt Hospital, were hurrying to the scene, the ambulance collided with a delivery wagon. One surgeon and the driver were thrown into the street, and an axle of the ambulance was broken. Finding the ambulance disabled, the surgeons seized the stretcher and ran on. The contractors engaged in constructing the section of the subway tunnel on Washington Heights have been hurrying along the work by using heavy blasts. One of these was so severe that it shook the building of the Hebrew Sheltering Guardian Society Orphan Asylum, causing plaster to fall from the ceiling in nearly every room, and pictures and ornaments to tumble from the shelves. The children ran through the corridors screaming with fright, and the superintendent was not able to get any satisfaction either from the contractors or from the police. The old question of abolishing the coroner's office received a new impetus by the spectacle which Coroner Goldenkranz made in connection with the dynamite disaster in the tunnel. Although he talked loudly about being "a constitutional officer," it should not be forgotten that this office was expressly stricken from the revised constitution in 1894 in order to make it easy for the legislature to abolish it. It is difficult to see why this has not yet been done, especially when the good example set by Massachusetts has been so long before us, but the time seems ripe for such action by the legislature.

#### Buffalo.

**Academy of Medicine.**—Dr. William R. Pryor, New York City, addressed the Section of Obstetrics and Gynecology of the Buffalo Academy of Medicine on "Pelvic Suppuration; When Shall We Operate by the Abdomen and When by the Vagina?"

**Personal.**—Health Commissioner Walter D. Green has appointed Dr. N. L. Burnham as city physician for the first district, to succeed Dr. George F. Cott, resigned. —Dr. Matthew D. Mann was elected president of the Society for Beautifying Buffalo. Dr. Mann is also one of the park commissioners. —Dr. Lucien Howe received a gold medal for the second time from the New York State Medical Society relative to a new staining process for the muscles of the eye.

#### NORTH CAROLINA.

**Personal.**—Dr. T. Evans McBrayer, Shelby, has been made surgeon to the S. C. and G. E. Railway. —Kennesville has a new physician, Dr. Andrew L. Wynn, who was formerly at Johnston Station, Ga.

**Medical Department of State University.**—The State University Department of Medicine is to be located at Raleigh. The faculty of the department, besides the dean, Dr. Hubert A. Royster, will include Drs. Richard H. Lewis, W. I. Royster, Dr. Augustus W. Knox, Kemp P. Battle, Jr., and others, who will be chosen by the executive committee.

**Wilmington Physicians Meet.**—At a recent meeting of the physicians of Wilmington over which Dr. Walter C. Galloway presided, Dr. Frank H. Russell, acting as secretary, Drs. William J. Love, Thomas S. Burbank, Frank H. Russell, and William D. McMillan were selected as visiting physicians to the James Walker Memorial Hospital. Drs. Lionel H. Love, Andrew H. Harris, G. K. Collier, N. M. Wetzel, R. Edgar Zachary, Thomas R. Little and Frank H. Russell were appointed to receive and entertain the State Medical Association.

**Medical Society of the State of North Carolina.**—This Society will hold its forty-ninth annual meeting at Wilmington, June 3 to 7. On the morning of the second day an entire new Board of Medical Examiners will be elected to serve for six years. The Pittman prize of \$100 will be awarded for the best essay on any medical subject. The president is Dr. Robert S. Young, Concord, and the secretary, Dr. George W. Pressly, Charlotte.

#### VERMONT.

**The Vermont Medical Monthly.**—The January number of this journal—the organ of the Vermont State Medical Society and of the Thurber County Medical Association—appears in an entirely new form and dress and considerably enlarged in size. These improvements show that the monthly is in a flourishing condition, which is certainly gratifying. One of the most encouraging signs is the fact that journals published by or for medical societies are in a prosperous condition and increasing in number.

#### CANADA.

**Notre Dame Hospital Quarantined.**—Smallpox has developed in one of the attendants at the Notre Dame Hospital, Montreal, and the whole institution will be under quarantine until the 12th of the month; there are over 200 patients in the institution.

**Big Increase in Smallpox.**—In Ontario 629 cases of smallpox developed during the month of January. The patients are scattered over twenty-eight counties with eighty-seven centers. Lecturing before the students of the Toronto School of Medicine on January 31, Dr. Hodgetts, provincial inspector, stated that the spread of the disease could be attributed to the ignorance of the profession.

**Blackmailing Doctors.**—Two well-known physicians of Toronto have during the past week been subjected to threats for the purpose of extorting money from them. When one of the physicians was visited in his office by the husband of a woman whom he had been called to attend and financial demands made upon him, he quickly laid a trap for his would-be blackmailer by requesting another interview, when he had a concealed witness present. The second physician had been called to attend the child of the family, and later the husband visited him at his office and made the same demands, claiming that his wife had been insulted. In this case he was shown the door. The case is now in the hands of the crown attorney.

**County Medical Inspectors.**—It is understood that the Ontario Government will be strongly pressed to amend the Ontario Health Act at the present session of the legislature to provide for the appointment of County Medical Health Officers, and at the same time fixing an adequate salary to be paid by each municipality for the proper performance of their duties. As at present constituted the act provides for township officers of health, but as the remuneration for this is only about \$50 to \$100 per annum, it can not be expected that any health officer is going to take charge of an epidemic of smallpox or other contagious disease for that paltry salary; hence the need of county officials with more powers and a larger remuneration.

**The Southwestern Medical Association of Manitoba.**—A few months ago this new medical association was organized among the practitioners of medicine in the southwestern part of the province of Manitoba and out of 70 available practitioners for membership in that district, no less than 67 have already become members, and there is every reason to believe that the remaining 3 will soon come in. This speaks well for an attempt at organizing the profession in Manitoba, as it is intended to carry on the good work of organization until the whole province is brought within its scope. The three main objects for the founding of this association are as follows: "We have decided to establish a new tariff for insurance companies and lodge work, which is as follows: Examination for admittance to lodges without insurance, \$2; examination for admittance to lodges with insurance, \$3; examination for admission to level premium insurance companies, \$5. All members of this Association have signed a pledge binding themselves to this tariff from January 1, 1902. The Association has also arranged a provisional tariff or fees to which all are to adhere as closely as possible. Then they have decided that members of the profession of medicine would be acting in their interests to send out quarterly statements of accounts, and that all contract work in relation to lodge practice should be discouraged.

#### FOREIGN.

**Annual Ball of the Paris Internes.**—The parade of the floats this year at the ball, December 16, represents the hos-

pitals of Paris, headed by the Hotel Dieu, showing "The Triumph of Cocain." The harvesting of the coca was first represented, then, after a group of physicians of antiquity and of the dark and middle ages, came the "Apostle of Spinal Cocainization." He was followed by a huge column portraying a spine with the needle inserted at the proper place. After this came the "inconveniences of cocain"—figures representing the headache, diarrhea, hemiplegia, etc., and finally a chariot with the "apotheosis of cocain." The Tenon hospital portrayed "the Northern Barbarians Returning from Mytilene with Mytilene (methylene) Blue."

**Overcrowding of the Profession in Belgium.**—The *Gazette Méd. Belge* states that the year 1901 continued the overcrowding of the profession. Parents are not discouraged by the difficulty of making a living from the honest practice of medicine. They see the rapid success of unscrupulous persons who disregard the ethics and dignity of the profession, and they push their sons into the medical courses advising them to mix a little charlatanism with their medicine. The average regular physician in Belgium earns at most 3000 francs a year, scarcely \$600. The *Gazette* adds that the number of patients is actually more than it was thirty years ago. If the number of physicians had not increased out of all proportion, the emoluments of the profession would be better than in the "good old days."

**Advertisements of Quacks in the German Dailies.**—The Munich local Aertzlicher Verein recently appealed to the lay press not to publish the advertisements of a certain notorious charlatan. Several of the dailies asserted in reply that the advertising department of a daily paper is not qualified to distinguish between fraudulent and bona fide medical advertisements. The *Augsb. Abendztg.*, however, added that all that a reputable paper can do and should do is to refrain from publishing the advertisements of notorious swindlers, and to lay before their readers all official or judicial revelations in regard to swindling operations conducted by advertisements, and besides this, should warn the public to keep its eyes opened. The press can never assume the office of official guardian of the public. The *Munich Med. Wochenschrift* considers this a valuable concession and, if realized, a great advance. It calls upon the local medical societies to have their press committees keep the papers posted in regard to "notorious swindlers."

**Alcoholism in Russia.**—It is difficult to say if it is well for the state to control the sale of spirituous liquors. There are two countries where this principle is carried out, Switzerland and Russia, and in the latter the results would not seem to be encouraging, from the temperance point of view. According to Dr. Fuster, who has seen the conditions obtaining in the different states of Europe, there is no country where so much intemperance exists as in Russia. On Sundays, for instance, drunkards are to be met in almost every street of the small towns. The police do not interfere in general. The shops where liquor is sold are only open at certain hours of the day, and crowds gather around their doors, each man holding in his hand an empty bottle which is to be exchanged for one containing alcohol at 40°. Two-thirds of a quart cost only twenty-two cents, but smaller bottles are sold for only four cents. Cases of death from alcoholic poisoning are not infrequent. Dr. Fuster expressed his opinion that the enactment of restrictive laws was not the best way of suppressing alcoholism, but rather the educating of the moral sense.

#### PARIS LETTER.

##### Methylene Blue in Buccal Infections.

Professor Chanfard has been trying methylene blue in certain forms of tonsillitis, especially in the ulcerative form. He considered that he had so good a result that for him it might serve as a means of differentiating ulcerative tonsillitis from chancre of the tonsil. Dr. Moizard, the celebrated child specialist, tried it in his service recently, and he told me that he had obtained no good result from its use, and he preferred to use tincture of iodine when in need of some energetic agent.

##### Eberth's Bacillus in the Blood in Typhoid Fever.

The presence of Eberth's bacilli in the blood in typhoid fever has been the subject of a good deal of discussion of late at the Medical Society of the Hospitals. Dr. Jules Courmont has

been carrying out investigations on this subject, and he declares that in ordinary forms of typhoid fever the bacillus is always found even before the fifth day. It remains in the blood until the end of the third week, and in certain prolonged forms with relapses it may remain even longer. There is no relation between the presence of bacilli in the blood and the agglutinating power of the serum, which is only seen very much later in some cases. A special method is needed, which consists in mixing two to four cubic centimeters of venous blood with five hundred cubic centimeters of bouillon. There are at times no results produced by using only a few drops of blood in a small quantity of bouillon. At a meeting of the Academy of Medicine this same subject was discussed, Dr. Chantemesse remarking that these investigations had already been carried out in Germany a year or two ago. According to Dr. Chantemesse, negative results had been obtained so far, because too much blood was added to the bouillon, and the serum prevented the growth of the bacilli.

#### Professor Jaccoud Retires.

Dr. Landouzy has been named professor of clinical medicine, succeeding to Jaccoud, who has been placed on the retired list. Dr. Gilbert, a professor agrégé of the School of Medicine, has taken Dr. Landouzy's place as professor of therapeutics. He is a relatively young man, being only forty-three years of age. Professor Landouzy, son of a distinguished physician, was chosen professor unanimously in 1893. He is well known for his aphorism on therapeutics, which he said should be "clinical, pathogenic, physiological and opportunist. Clinical as to its sources of information, pathogenic in its indications, physiological as to the means employed, and opportunist in the decisions that are reached."

#### New Treatment for Sprains.

A new treatment for sprains is being advocated. It consists in the use of electricity. Several English authors have, it seems, spoken vaguely about its use, and Remak, the German author, recommends the use of the continuous current, according to Tripiér. Apostoli, however, believed in faradization, and such is the method which has given so far the best results. The electrodes consist of two large tampons of coal covered with chamois skin and the negative pole is placed and moved over the injured spot. The sitting only lasts five to ten minutes, and produces so rapid a result that the patient can sometimes walk immediately after. Two applications of electricity should be made every day in some cases, and rapid improvement will be noticed.

#### Census of 1901.

The census taken in France in 1901 shows that the population is increasing very slowly. The results showed an increase of 444,613 inhabitants during the last five years, which is much better than during the period from 1891 to 1896, when the increase was only 175,027. Other nations are increasing much more rapidly, the population of Germany has increased about 7,000,000 during the last ten years, that of Austria-Hungary 4,000,000, and that of Great Britain about 5,000,000.

#### Biliary Lithiases.

Dr. Pauchet, a former interne of the Paris hospitals, speaking of an operation for spontaneous rupture of the biliary vesicle with recovery, remarked recently that there was no medical treatment of biliary lithiases, and drew a parallel between a stone in the bladder and one in the vesicle. Cholecystotomy was no more dangerous an operation than cystotomy.

#### Paris Seeking Better Milk Supply.

The milk supply of Paris is being extensively discussed at present in the political papers, especially in the *Matin*, which has instigated a crusade against milkmen who adulterate the product they sell. A league is to be formed called the League for the Defense of Human Life. The *Matin* has published most energetic articles, describing the methods used. Milk is sometimes sold directly to the buyer, and in such cases there is not much chance for adulteration. In other cases milk is first collected from producers outside Paris, then brought in and sold to the dealer by a third party, so that it passes through four intermediaries. Milk which is bought outside Paris at from 9 to 11 centimes the quart costs from 40 centimes to a franc inside Paris. Not only is milk more or less modified by the use of various concoctions, but it is also sensibly diluted by the use of water. The new league will prosecute directly for its members and police supervision of milkmen has become of late more efficient.

## Association News.

### New Members.

The following is a list of new members of the American Medical Association for the month of January, 1902.

#### ALABAMA.

Betts, W. F., Evergreen.  
Peacock, L. E., Blocton.

#### ARKANSAS.

Russmunn, W. C., Helena.  
Montgomery, W. A., Atkins.  
Warren, G. A., Imboden.  
Tarrant, J. R., Monticello.

#### CALIFORNIA.

McMurdo, J. R., San Francisco.  
Henderson, J. J., San Francisco.  
Williamson, J. M., San Francisco.  
Ebright, G. E., San Francisco.  
Power, H. D. A., San Francisco.  
Fitzgibbon, G. J., San Francisco.  
Plymire, D. B., San Francisco.  
Johansen, Ernest, San Francisco.  
McIntosh, A. M., San Francisco.  
Cross, W. W., Visalia.  
Still, J. J., Los Angeles.  
Dundas, R. C., Los Angeles.  
Colburn, J. R., Los Angeles.  
Cates, H. G., Los Angeles.  
Phelp, W. S., Los Angeles.  
Smith, E. R., Los Angeles.  
Mathis, E. N., Los Angeles.  
McCarthy, D. S., Los Angeles.  
Hitt, M., Los Angeles.  
McCoey, T. J., Los Angeles.  
Morrison, N. H., Los Angeles.  
Taggart, C. F., Los Angeles.  
Pahl, P. C. H., Los Angeles.  
Pottenger, F. M., Los Angeles.  
Swearingen, S. P., Pasadena.  
Gochenauer, D., San Diego.  
Edwards, W. A., Corona.  
Corbin, F. E., Los Angeles.  
Dial, E. A., San Luis Obispo.

#### CONNECTICUT.

Benedict, F. A., Seymour.  
Brown, C. H., Waterbury.  
Sperry, F. N., New Haven.

#### COLORADO.

Mayne, O. J., Como.  
Gorsuch, J. C., Denver.  
Ostrander, F. W., Idaho Springs.

#### DISTRICT OF COLUMBIA.

Miller, W. L., Washington.

#### FLORIDA.

McMillan, D. W., Pensacola.

#### GEORGIA.

Youmans, L. P., Swainsboro.

#### INDIANA.

Evans, E. B., Greencastle.  
Jackson, F. G., Muncie.  
Hollis, S., Hartford City.  
Carter, W. J., Converse.  
Faith, A. H., Washington.  
McSherry, J. L., Sulphur Springs.  
Potter, J. E., Milford.  
Mueller, F. M., Lawrenceburg.  
Sherman, W. C., Loogootee.  
Welburn, J. Y., Evansville.  
Metts, Fred, Ossian.  
Held, H. W., Vincennes.  
Calvin, W. D., Ft. Wayne.  
Doerr, J. E., Mt. Vernon.  
Holton, W. M., New Harmony.  
Hall, H. M., Millersburg.  
Davenport, W. H., Vincennes.  
McDowell, M. B., Vincennes.  
Reeves, E. W., Plymouth.

#### ILLINOIS.

Frick, A., Chicago.  
Black, A. D., Chicago.  
Wells, W. H., Monmouth.  
Schrading, W. P., Palatine.  
Johnson, C. B., Batavia.  
Warbrick, J. C., Chicago.  
Swenson, C. G., Chicago.  
Clark, E. J., Winnebago.  
Neiswanger, C. S., Chicago.  
Humiston, C. E., Chicago.  
Barker, L. F., Chicago.  
Schmidt, F. W., Chicago.  
Macanley, T. E., Gilberts.  
Shastid, W. E., Pittsfield.  
Miller, A. E., Metropolis City.  
Schlernitzauer, Wm., Freeburg.  
Healy, W., Chicago.

#### IDAHO.

Castle, H. A., Pocatello.

#### IOWA.

Hess, W. C., Bagley.  
Skelley, W. F., Lost Nation.  
Kessler, J. B., Iowa City.  
Watson, S. H., Blairtown.

#### KENTUCKY.

Chandler, W. S., Mt. Olivet.  
Richards, W. A., Morganfield.  
Sage, E. O., Louisville.  
Reed, J. A., Maysville.

#### KANSAS.

Manning, H. W., Eureka.  
Oldham, Jas. E., Wichita.  
Graves, A. C., Pittsburg.  
Whinery, S. C., Kansas City.

#### LOUISIANA.

Jones, R. P., Clinton.  
Hays, G. A. B., Jackson.

#### MARYLAND.

Cloggett, Sam'l, Petersville.  
Perry, J. P., Clearspring.  
Simmons, H. M., Baltimore.  
Shannon, Geo. C., Baltimore.  
Maxwell, W. S., Still Pond.

#### MASSACHUSETTS.

Bonney, C. A., Jr., New Bedford.  
Kelleher, P. F., Cambridge.  
Kearney, J. H., Fitchburg.  
Hutchinson, C. M., Cambridge.

#### MAINE.

Jonah, W. E., Portland.

#### MONTANA.

Turner, C., Butte.  
Spottswood, E. W., Missoula.  
McIntyre, John, Butte.  
Roberts, H. C., Great Falls.  
Lindsey, Chff, Billings.  
Gunn, J. W., Butte.

#### MICHIGAN.

Wallace, J. J., Sparta.  
Wight, W. G., Yale.  
Croman, J. M., Mt. Clemens.  
Noyes, G. L., Ann Arbor.  
Marvin, H. M., Coloma.  
Jenks, H. D., Detroit.  
Jacklin, J., Saginaw.

#### MISSOURI.

Triplett, J. S., Harrisonville.  
Latt, G. W., Westboro.  
Anthony, F. R., Maryville.  
Frankenburger, J. M., Kansas City.  
Marfit, J. C., St. Louis.

#### NEBRASKA.

Bicknell, G. H., Omaha.  
Davies, R. A., Arlington.  
Hay, J. T., Lincoln.  
Mullins, C. L., Broken Bow.  
Hamilton, A. G., Springfield.  
Poska, Abraham, Lincoln.  
Brash, G. H., Beatrice.  
Sward, E. J. C., Oakland.  
Hickok, H. S., Carleton.  
Finley, H. L., Pawnee City.  
Deardorf, B. M., Clatonia.  
McKibbin, J. W., Adams.

#### NEW HAMPSHIRE.

Hazleton, G. W., Haverhill.  
Staples, J. W., Franklin Falls.  
Walker, C. S., Concord.  
Towle, F. S., Portsmouth.

#### NEW JERSEY.

Wickham, A., Newark.  
McNamara, T. C., Hoboken.  
Whitehead, R. B., Elizabeth.  
Steadman, W., Hoboken.  
Shalier, S., Newark.  
O'Donnell, J., Paterson.  
McLaughlin, G., Jersey City.  
Dunlap, Mary J., Vineland.  
Morris, C., Newark.  
Weigand, O. A., Jersey City.

#### NEW MEXICO.

Lané, B. E., Las Cruces.

#### NEW YORK.

Beach, Judson, Etna.  
Biggam, W. H., Brooklyn.  
Ayne, E. L., New York.  
Morton, H. H., Brooklyn.  
Curry, G. P. M., Mt. Kisco.

Sharp, E. A., Central Valley.  
Cronson, R., New York City.  
Hartley, F., New York City.  
Welr, R. F., New York City.  
Ayers, E. A., New York City.  
Webster, David, New York City.  
Chappell, W. F., New York City.  
Foote, E. M., New York City.  
Dolz, Wm., New York City.  
MacKeen, A. L., New York City.  
Wood, L. C., Poughkeepsie.  
Little, W. E. E., Bloomington.  
Lyle, Alex., New York City.  
Abbe, Robt., New York City.  
Bernard Sachs, New York City.  
Kinnicott, F. P., New York City.  
Rupp, Adolph, New York City.  
Sherman, A. L., New York City.  
Pollitzer, Sigmund, New York City.  
Ladinski, L. J., New York City.  
Keller, F. C., New York City.

#### NORTH CAROLINA.

McKee, Jas., Raleigh.

#### NORTH DAKOTA.

Henning, J. D., Fargo.  
Brimi, C. L., Cooperstown.

#### OHIO.

Jones, J. A., Cleveland.  
Courtright, F. E., Shawtown.  
Ballard, C. B., Marietta.  
Tucker, W. H., Glen Karn.  
Weaver, W. P., Miamisburg.

#### OKLAHOMA.

Dicken, W. E., Oklahoma.  
Jordan, J. E., Stella.  
Share, A. L., Kingfisher.  
Chandler, H. S., Woodward.  
Salmon, W. T., Oklahoma City.

#### OREGON.

Dickson, J. F., Portland.  
McGavin, J. M., Portland.  
Tucker, E. F., Portland.  
Shane, L. A., Portland.  
Jones, Wm., Portland.  
Johnson, E. D., Portland.

#### PENNSYLVANIA.

McLean, J. D., Philadelphia.  
Raine, A. R., Philadelphia.  
Grover, J. B., Peckville.  
Smyser, H. David, York.  
Free, G. B. M., Danville.  
Hamilton, W. T., Philadelphia.  
Evans, D. W., Scranton.  
Wilkins, J. W., Philadelphia.  
Willson, R. N., Philadelphia.  
Wade, F. H., Allegheny.

#### SOUTH DAKOTA.

Merager, O. S., Sioux Falls.  
Bliss, G. W., Valley Spring.  
Thompson, J. R., Northville.  
Arnold, D. E., Hecla.  
Pickering, L. A., Warner.  
Olney, S., Sioux Falls.

#### TENNESSEE.

Preston, J. H., Humboldt.  
Smith, S. B., Nashville.

#### TEXAS.

Weems, M. L., Brazonia.  
Burrows, H. A., New Boston.  
Gibson, B. F., Midway.  
McCobb, G. W., Gonzales.

#### VERMONT.

Lewis, H. E., Burlington.

#### VIRGINIA.

Saunders, C. A., Norfolk.  
Baughman, Green, Richmond.  
Hallar, J. P., Pocahontas.  
Smith, H., Norfolk.  
Royster, L. T., Norfolk.  
Detwiler, E. L., Herndon.  
Williams, E. G., Richmond.  
Gwathoney, Norfolk.  
Kennis, B. R., Norfolk.

#### WASHINGTON.

Miller, F. C., Tacoma.  
Ingham, G. W., Olympia.  
Carroll, F. M., Seattle.  
Baker, N. M., Spokane.  
Gray, G. A., Spokane.  
Smith, Harvey, Spokane.  
Loughlen, O. W., Tacoma.  
Peterkin, G. S., Seattle.  
Gunn, T. B., N. Yakima.  
Overmeyer, G. W., Aberdeen.  
Ludlow, W. L., Seattle.  
McCreedy, N. S., Snowhomish.  
Compton, H. A., Fairhaven.  
Birney, H. J., Whatcom.  
Powell, J. M., Spokane.  
Ford, C. B., Seattle.  
Chalmers, J. M. P., Vancouver.  
Markley, L. R., Whatcom.

#### WISCONSIN.

Morse, A. J., Fond du Lac.  
Gray, A. W., Milwaukee.  
Stalker, H. J., Kenosha.  
Bertrand, J. H., De Forest.  
Manchester, B. E., Armstrong Creek.  
Chanon, T. A., Rice Lake.

#### WYOMING.

Carton, Jas., Carbon.

juries of the Ear," and "On the Ear." He was a member of the American Otological Association, the Philadelphia College of Physicians, Philadelphia County Medical Society and the Philadelphia Pathological Society. He was founder of the Philadelphia Infirmary for Diseases of the Ear, of which he was also chief of staff, and was also aurist to the Presbyterian Hospital.

**Robert B. Grimes, M.D.** Washington University, St. Louis, 1869, died from apoplexy, January 27, aged 58. "Fighting Bob, the Doctor," as he was known, served throughout the War of the Rebellion, and was discharged as lieutenant. After his graduation in medicine he entered the medical department of the Army, and was honorably mentioned for bravery in the dispatches. He was a member of the Thornburg expedition that went to the relief of the White River agency in September, 1881, and was one of the few that survived. When Thornburg and his party were attacked, Dr. Grimes, as chief surgeon of the expedition, not only attended the wounded, but found time to make coffins, to assist in the burial of the dead, to throw up breastworks, to bring water to the soldiers in the pits and occasionally take a shot at a redskin himself. Though dangerously wounded, he continued on duty for days till the survivors were rescued.

**Dominick G. Bodkin, M.D.** New York University, 1866, died at his home in Brooklyn, January 26, after a long illness, from gastric ulcer, aged 68. While a medical student he volunteered for service in the Civil war, and was placed in charge of the smallpox and fever hospitals at Dauphin Island and Fort Gaines. He lived and practiced in Brooklyn from 1866. He was a member of the American Medical Association, New York State Medical Association, Kings County Medical Society and Long Island Medical Association. For many years he was chief of staff of St. Mary's Hospital. He was a delegate to the International Medical Congress of Moscow in 1897.

**S. Seabury Jones, M.D.** New York University, 1869, who studied in Edinburgh and Berlin and practiced thereafter in New York City, died at his home, January 21, from pneumonia, after an illness of three days, aged 55. He was a member of the Academy of Medicine, the Manhattan Medical and Surgical Society, and the Lenox Society, and was consulting physician at the workhouse and the almshouse.

**Francis Clemens, Jr., M.D.** University of Pennsylvania, Philadelphia, 1899, a practitioner of Paoli, Pa., was drowned while attempting to cross a flooded stream in Willistown township, January 22. He was returning from a professional call. His brother-in-law, Mr. George Davis, a senior student in the Medico-Chirurgical College, Philadelphia, was also swept down the stream, but was rescued.

**Harry G. Willson, M.D.** University of Pennsylvania, Philadelphia, 1895, of Laporte, Pa., died, after a long illness, at the residence of his parents in Warrensville, January 21, aged 32. He was a member of the American Medical Association and of the Lycoming County Medical Society. The latter Society, at a special meeting held January 22, at Williamsport, adopted resolutions of sympathy.

**Agnes M. Gardiner, M.D.** Woman's Medical College, Philadelphia, 1899, a member of the staff of the Toledo State Hospital, and a daughter of Dr. William G. Gardiner, was found dead in bed, January 25. The cause of death is stated to be apoplexy. Dr. Gardiner was 23 years old, and was a member of the American Medical Association.

**Charles G. Sproull, M.D.** New York University, 1893, afterward an interne in Bellevue Hospital, a practitioner of New York City and one of the incorporators of the Skene Hospital for Self-Supporting Women, died at the private hospital of Dr. W. T. Bull, where he had been operated on for appendicitis, January 24, aged 34.

**Ora S. Pease, M.D.** Dartmouth Medical College, Hanover, N. H., 1880, a well-known practitioner of Penobscot County, Me., and a resident of Old Town, died at the City Hospital, Old Town, January 18, as the result of a fall three weeks previously, aged 55. He was one of the founders of the Old Town City Hospital.

**William Hannibal McClure, M.D.** Atlanta (Ga.) Medical College, 1875, who served as member of the legislature and as state senator in Georgia and moved to Westminster, S. C., in 1895, died at his home in that city, January 19, from Bright's disease, after a long illness, aged 52.

**Andrew J. Hines, M.D.** Jefferson Medical College, Philadelphia, 1853, the oldest practitioner in Doylestown, Pa., and a prominent member of the Bucks County Medical Society, died

### Married.

U. TOPE, M.D., to Miss Annie Talcott, both of Scio, Ohio, January 22.

AMBRIS C. PICKETT, M.D., to Miss Lucy Sanders, both of Woodlawn, Mo., January 26.

LINUS WARD KLINE, M.D., to Miss Fannie Talbot Littleton, at Suffolk, Va., January 23.

MIDDLETON L. PERRY, M.D., to Miss Janie Wimberly, both of Milledgeville, Ga., January 19.

WALTER B. STEWART, M.D., to Miss Gertrude Louise Sawyer, both of Joliet, Ill., January 22.

ANDREW B. EATON, M.D., Eaton's Cross Roads, Tenn., to Miss Mae Bull, of Kingston, Tenn., January 8.

CHARLES D. MCGETTIGAN, M.D., Captain and Assistant Surgeon, N. G. C., San Francisco, to Miss Francesca C. Vallejo, daughter of Dr. Peaton Vallejo and grand-daughter of General Vallejo, at San Francisco, January 22.

### Deaths and Obituaries.

**Charles H. Burnett, M.D.** University of Pennsylvania, 1867, died at his home in Bryn Mawr, near Philadelphia, January 31, aged 60. After his graduation he served one year as interne in the Episcopal Hospital and then studied abroad for two years, devoting his attention especially to otology. On his return he commenced practice in Philadelphia, making a specialty of diseases of the ear, and in this department soon took a leading position. His contributions to otologic literature have been numerous and valuable, chief among them are "A System of Diseases of the Ear, Nose and Throat," "Diseases and In-

at his residence, January 21, from kidney disease, after a prolonged illness, aged 76.

**Benjamin D. Blackstone, M.D.** Western Reserve University, Cleveland, 1848, a resident and practitioner of Martinsville, Ind., for more than half a century, died at his home in that city, January 23, after a long illness, aged 77.

**H. U. Umstad, M.D.** Jefferson Medical College, Philadelphia, 1851, the oldest practitioner in Chester County, Pa., died at his home in Phoenixville, January 26, from Bright's disease, after an illness of one year, aged 75.

**John H. Harley, M.D.** University of Maryland, Baltimore, 1857, who had practiced medicine at Dewart, Northumberland County, Pa., for more than forty years, died January 14, at his home, from pneumonia, aged 75.

**Lachlan Tyler, M.D.** Columbia University, New York, 1876, who had been connected with the New York Board of Health for several years, died shortly after an operation for appendicitis, January 27, aged 50.

**F. J. Spilman, M.D.** Medical College of Ohio, Cincinnati, 1858, who had practiced medicine for nearly half a century at Andersonville, Ind., died at his home in that place, January 23, from jaundice, aged 70.

**Edmund R. Hebrank, M.D.** University of Maryland, Baltimore, 1889, one of the best-known physicians of Westmoreland County, Pa., died at his home in Adamsburg, January 23, from consumption, aged 48.

**George H. Stone, M.D.** Albany (N. Y.) Medical College, 1898, a practitioner of Forestdale, Vt., died in Albany, N. Y., January 23, from tuberculosis, after an illness of four months, aged 28.

**John A. Northrup, M.D.** Geneva (N. Y.) Medical College, 1866, a practitioner and postmaster of Dover, Okla., died at his home in that place, January 17, after a prolonged illness.

**Joseph Morris, M.D.** University of Michigan, Ann Arbor, 1861, an esteemed practitioner of Columbus Grove, Ohio, died at his residence, January 24, from pneumonia, aged 63.

**Benjamin Franklin Pope, M.D.** University of Nashville, Tenn., a prominent citizen of DuQuoin, Ill., died January 24, at his home, after an illness of two years, aged 76.

**George W. Bellus, M.D.** Rush Medical College, Chicago, 1878, one of the pioneer physicians of Taylor County, Iowa, died at his home in Blockton, January 12, aged 65.

**William R. Wells, M.D.** Harvard University, 1834, the oldest practitioner in Sonoma County, Cal., died at his home in Petaluma, January 24, aged 88.

**Nathan M. Babad, M.D.** Columbia University, New York, died from consumption at the Good Samaritan Hospital, Los Angeles, January 21, aged 29.

**John Wesley Martin, M.D.**, the oldest physician of Brookhaven, Miss., died January 25, after a month's illness, aged 81.

**D. M. Anderson, M.D.**, an old resident of Texas, died at his home in Brownwood, January 23, aged 71.

## State Boards of Registration.

**District of Columbia Examination.**—The regular quarterly examination for license was held January 9 to 13 at Washington. The number of subjects examined in were 15; number of written questions, 80, with additional oral examination. Total number of candidates was 12, of whom 8 passed.

**Delaware Examiners Appointed.**—The following physicians have been appointed by Governor Hunn to the State Board of Medical Examiners: Dr. Edwin S. Anderson (H.),

Dover; Dr. Francis L. Springer, Newport (R.); Dr. A. E. Frantz (H.), Wilmington; Dr. E. W. Cooper, Camden (R.). The appointment is for two years.

## Miscellany.

**Potassium Permanganate in Dysentery.**—Kuzmitzky reports very favorable results from the treatment of dysentery with rectal injections of a 1 to 4000 tepid solution of potassium permanganate, twice a day.—*Woenn-Med. Journal*, for November.

**Equine Morality!**—An Eastern weekly contemporary notices a recent febrile disease affecting horses in the Island of Luzon and "resulting in a great morality." If that is all it might not be an ill chance should it affect some of the human inhabitants there also. The government laboratories could possibly find a mitigated form valid against faith-breaking, etc., to inoculate the biped Tulisanes and insurgent prisoners with and thus insure their better behavior.

**Consolidation of Cleveland Medical Journals.**—An event significant of the tendencies of the time has just occurred in Cleveland. Plans for the amalgamation of the *Cleveland Journal of Medicine* and the *Cleveland Medical Gazette* have been brought to a successful issue. On January 20, 1902, was held the organization meeting of the *Cleveland Medical Journal Company*, which is composed of those physicians now interested in the two old journals, together with a good proportion of the representative physicians of Cleveland, numbering in all 45 stockholders. At a considerable sacrifice on the part of many, the two old journals have been transferred in their entirety to the new company that will publish the new journal, which is to be an independent and free professional institution conducted for the good of the medical community, with no idea upon the part of the stockholders that they shall ever look for dividends. At this meeting a temporary organization was formed, consisting of Dr. Marcus Rosenwasser, president; Dr. William E. Bruner, secretary; Dr. Joseph F. Hobson, treasurer. Dr. P. Maxwell Foshay was elected editor, and Dr. Edward S. Lauder, associate editor.

**The American Medical Association.**—The following circular letter has been issued by John A. Wyeth, M.D., president of the American Medical Association: Every practitioner who believes it necessary and wise to safeguard the material interests of the medical profession, to foster the growth and diffusion of medical knowledge, to promote friendly intercourse among American physicians, to elevate the standard of medical education, to secure the enactment and enforcement of medical laws, to enlighten and direct public opinion in regard to the problems of State medicine, and to represent to the world the practical accomplishments of scientific medicine, and who accepts the most important lesson of human experience that without organization controlled by judicious discipline there can be no coöperation between large groups of men, and no satisfactory or successful outcome to their labors, should either join, or lend his influence to, the American Medical Association, the one great aim of which to is federate into one compact organization the medical profession of the United States. He should join it in preference to any sectional medical association, because it is the *only representative national organization of the profession in the Union*. It has representative societies in every State and Territory of the United States. Its comprehensive scheme embraces the formation in every county of a medical society, with a uniform constitution and by-laws, each of which shall belong to the State association, organized and governed with equal uniformity, and all a part of the national body. In the reorganization at St. Paul in 1901, the question of eligibility to membership in this vast body was referred directly to the primary or county societies. "No person not a member of his local affiliated medical society, provided there be one, shall be eligible to membership, or be allowed to continue as a member in the Association." This ruling dropped temporarily a considerable number who had

long been on the roster as permanent members from State or local bodies which, by the by-laws then existing, made them eligible. While this action may, at first glance, seem unnecessarily severe or even unjust to those older members (among whom are many of the most loyal and faithful supporters of the national body), reflection must convince them that not only should they yield to the opinion of the majority, but approve the wisdom of this policy. In no other way could the exclusion of unworthy persons be secured than by having those who are intimately acquainted with the moral character and professional standing of the applicant pass upon his merits. No other organization can compare with the American Medical Association as a working machine, capable of carrying to successful completion the great work of uniting the medical profession. Its officers are men long trained in a work which requires not only experience but tact and business ability. It owns not only a surplus fund, which enables it to move with strength and confidence in the accomplishment of its purpose, but it has as its most active agent a weekly medical periodical, *THE JOURNAL of the American Medical Association*, which has a larger circulation than any similar periodical in the world. It maintains a National Committee on Medical Legislation, located in Washington City, and in this central committee every State and Territory in the United States has its membership. The State and county legislative sub-committees, reaching to all the Congressional districts and in touch with the affairs of the State, can not fail to wield a powerful influence in all affairs connected with medical legislation. To direct legislation in all matters pertaining to the public health, to inter-continental, insular and interstate quarantine, as well as to maintain and to further improve the laws relating to the practice of medicine, and to the requirements of medical education is the prerogative of the medical profession. It is the plain duty of all to help in bringing about this "consummation devoutly to be wished" by joining the American Medical Association.

## Societies.

**Yakima County (Wash.) Medical Association.**—At the annual meeting of this Association in North Yakima, January 11, Dr. Thomas B. Gunn was elected president; Dr. B. A. Owens, Adair, vice-president, and Dr. David Rosser, secretary.

**Wapello County (Iowa) Medical Society.**—The annual meeting of this Society was held at Ottumwa, January 7. Dr. Benjamin W. Searle, Ottumwa, was elected president; Mark D. Pascoe, Ottumwa, vice-president, and Dr. Emma S. Powell, secretary-treasurer.

**Will County (Ill.) Medical Association.**—The annual business meeting of this organization was held at Joliet, January 14. Dr. Thomas H. Wagner, Joliet, was elected president; Dr. Watson H. Curtis, Wilmington, vice-president, and Dr. H. S. Worthley, Joliet, secretary-treasurer.

**Lorain County (Ohio) Medical Society.**—At a recent meeting of the Society the following officers were elected: President, Dr. Washington Foster, North Amherst; vice-president, Dr. Olney B. Monosmith, Lorain; secretary, Dr. C. F. Gilmore, Lorain, and treasurer, Dr. Frank Young, Lorain.

**Clark County (Ky.) Medical Society.**—At the annual meeting of this Society in Winchester, January 11, Dr. Nelson V. Prewitt, Winchester, was elected president; Dr. C. G. Stephenson, vice-president; Dr. Isaac A. Shirley, Winchester, secretary, and Dr. John A. Snowden, Wade's Mill, treasurer.

**Litchfield County (Conn.) Medical Association.**—At the quarterly meeting of this body held at Torrington, January 14, a banquet was given by the local members. Dr. John C. Kendall, Norfolk, was elected president; Dr. Jerome S. Bissell, Torrington, vice-president, and Dr. A. E. Cobb, Falls Village, clerk.

**Central Texas Medical Association.**—This Society met at Belton, January 14 and 15. Dr. Frank D. Thompson, Fort Worth, was elected president; Dr. M. P. McElhannon, Belton, vice-president, and Dr. William R. Thompson, Fort Worth, secretary and treasurer. The next meeting will be held at Waco.

**Winona County (Minn.) Medical Society.**—The annual meeting of this Society was held in Winona, January 7. The

following officers were elected: Dr. Charles A. Boyd, Lewiston, president; Dr. Leland H. Munger, Winona, and Dr. Lynch, vice-presidents; Dr. James B. McGaughey, Winona, secretary; and George J. Tweedy, Winona, treasurer.

**York County (Maine) Medical Society.**—The eighth annual meeting of this Society was held in Biddeford, January 9. The election of officers resulted as follows: Dr. Henry I. Durgin, South Eliot, president; Drs. Charles W. Blagden, Sanford, and Jesse D. Haley, Saco, vice-presidents; Dr. Lawrence E. Willard, Saco, secretary, and Dr. J. Starr Barker, Kennebunk, treasurer.

**Dutchess County (N. Y.) Medical Association.**—The first annual meeting of this Association was held at Vassar Hospital, Poughkeepsie, January 8. Dr. Irving D. LeRoy, Pleasant Valley, was re-elected president; Dr. Henry E. Allison, Fishkill Landing, secretary, and Dr. Louis C. Wood, Poughkeepsie, treasurer. The dates of the semi-annual meetings were changed to the fourth Wednesday in April and October.

**Columbia County (N. Y.) Medical Association.**—At the first annual meeting of this Association, held in Hudson, January 14, Dr. Thomas Wilson, Hudson, was re-elected president; Dr. H. Lyle Smith, Hudson, vice-president; Dr. O. Howard Bradley, Hudson, secretary and treasurer; Dr. Crawford E. Fritts, Hudson, delegate to the New York State Medical Association, and Dr. T. Floyd Woodworth, Kinderhook, alternate.

**Warren County (N. Y.) Medical Association.**—The annual meeting of this Association was held in Glens Falls, January 8. Dr. David J. Fitzgerald, Glens Falls, was elected president; Dr. Daniel B. Howard, Warrensburg, vice-president; Dr. Fred G. Fielding, Glens Falls, secretary and treasurer, and member of nominating committee for State Association, and Dr. William J. Hunt, Glens Falls, fellow of the State Association.

**Medical Society of the District of Columbia.**—At a recent meeting of this Society the following officers were elected to serve during present year: President, Dr. Samuel S. Adams, Washington; vice-presidents, Drs. John W. Chappell, Tennytown, and Aurelius R. Shands, Washington; treasurer, Dr. Charles W. Franzoni, Washington; corresponding secretary, Dr. Thomas C. Smith, Washington; recording secretary, Dr. Francis P. Morgan, Washington, and librarian, Dr. Edwin L. Morgan, Washington.

**Atchison County (Mo.) Medical Association.**—The physicians of Atchison County met on January 7 at Rock Port, organized the above association and adopted a constitution. Meetings are to be held quarterly—the next one on April 2 at Fairfax. Of the twenty odd physicians in the county, fourteen were present. The president is Dr. J. A. Postlewait, of Tarkio, the secretary, Dr. Austin McMichael, of Rock Port, and the treasurer, Dr. Hunter, of Fairfax. At this meeting Dr. E. E. Richards, of Tarkio, read a paper on "Pneumonia," emphasizing especially streptococcus pneumonia. Dr. G. W. Lott read a paper on "Diphtheria." In this connection Dr. Holliday, of Tarkio, maintained the non-identity of diphtheria and membranous croup, and Dr. Ladd, of Westboro, the non-specificity of antitoxin. Both these positions were contested by Dr. J. I. Small, of Fairfax.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*Ninety-sixth Annual Meeting, Held in Albany,  
Jan. 28-30, 1902.*

The President, Dr. Henry L. Elsner, of Syracuse, in the Chair.

FIRST DAY—TUESDAY, JANUARY 28.

### Inaugural Address.

DR. HENRY L. ELSNER, of Syracuse, delivered this address, and, according to custom, made certain recommendations, which were then referred to a committee for consideration and report. He pointed out the danger of accepting unreservedly the views recently promulgated by Koch regarding the question of the communicability of bovine tuberculosis to human beings. He also recommended that the Society take an active interest in the furtherance of the project to establish a national bureau of health. The semi-annual meeting of the Society, held last October in New York City, as an experiment having proved so successful, Dr. Elsner suggested that the officers consider the advisability of holding such a meeting this year in some other city than Albany, preferably in Buffalo. A significant feature of the address was the speaker's declara-

tion that the delegate system of the State Society should be abolished.

#### Proposed Union of the Two State Organizations.

DR. ELSNER then considered the proposition to unite the medical profession of the Empire State in one harmonious organization. He introduced the subject with the assertion that the American Medical Association had been practically reorganized on a broad and liberal basis, and that the old code of ethics quarrel was a dead issue. He was confident that the desired unification of the profession in New York State could be effected with dignity and without the sacrifice of principles. Readers of THE JOURNAL are already familiar with the overtures made by the Medical Society of the County of New York to the New York County Medical Association, and the cordial way in which they were received by the latter body, although their charter made it necessary to refer such a question to the State Association. But these occurrences were but the heralds of the dawn, and many in the profession have been waiting impatiently for the full light of day—for action rather than mere expression of opinion. On this point Dr. Elsner said: "I recommend that the Medical Society of the State of New York appoint a committee of five to confer with an equal number representing the New York State Medical Association for the purpose of formulating a plan which shall have for its object the reorganization of the regular profession, which body shall be in affiliation with the American Medical Association, and that the committee report the result of its labors at the next meeting of the Medical Society of the State of New York. In the event of the failure of the New York State Medical Association to appoint such a committee, or if the committees should fail to agree upon a plan of reorganization, the committee appointed by the Medical Society of the State of New York shall have full power, if it deems it expedient, to represent the Society before the American Medical Association, and the Secretary of this Society shall, if the majority of the committee desires, provide the individual members with credentials of delegates to the American Medical Association. The method of election or appointment of the committee representing this Society shall be decided by the committee to which the president's inaugural address shall be referred, and shall be ratified, as are all recommendations, by a vote of the Society." It should be added that this committee gave this recommendation its unqualified approval, and the Society accepted the suggestion that Dr. Henry L. Elsner be made the chairman of the committee of conference with power to select as his associates four representative members of the Society. These appointments will be made in a few days, and the New York State Medical Association will then be officially notified of the action taken.

#### Goiter—Its Medical and Surgical Treatment.

DR. THOMAS P. SCULLY, Rome, presented a paper with this title, based on a personal experience with 47 cases. He advocated treatment of parenchymatous goiters by injecting into them a mixture of equal parts of tincture of iodine and a 5 per cent. solution of carbolic acid, using from 10 to 30 minims at a time, and making the injection once a week in a different spot. Galvano-puncture was also useful. Cystic goiters should be treated surgically, the mortality being quite low, only 1 per cent. in 2000 cases treated by Professor Kocher.

#### What Shall Be Done with the Professional Midwife?

DR. M. J. LEWIS, of New York, presented a paper on this subject, in which he pointed out the large number of midwives regularly practicing in a large city like New York, and the many evils resulting from allowing ignorant women to act in such a capacity. It was suggested that the Committee on Legislation should draft a bill with the hope that the legislature could be prevailed upon to enact a law which would serve to restrict, though not abolish, the midwife. The committee was then directed by special resolution to endeavor to carry out the views expressed in the paper and by those who discussed it.

#### Human Asymmetry.

DR. W. S. ELY, Rochester, pointed out many points of asymmetry, such as inequalities in the length and circumfer-

ence of the lower extremities, unequal power in the two eyes and the two ears, the lack of symmetry in the lungs, the kidneys and even the heart itself. The recognition of these facts were shown to have a practical value, as for example, in making deductions from the results of physical examination.

#### Sarcoma of the Tonsil.

DR. ARTHUR G. ROOT, Albany, reported this case, occurring in a man of 23, and necessitating lateral pharyngotomy.

#### Treatment of Pelvic Suppuration.

DR. CHARLES P. NOBLE, Philadelphia, presented a paper on this subject, based upon 200 cases. He showed that the mortality had fallen from 16.3 per cent. in the earlier cases to 4.8 per cent. in the later ones. Most of the latter had been treated by incision through the vault of the vagina.

#### The Sideroscope.

DR. THOMAS R. POOLEY, New York City, exhibited the improved instrument of Hirschberg, and said that he was the first to employ the magnetic needle for detecting the presence of particles of iron and steel in the eye. His first paper on this subject had been presented in 1880 to the Section on Ophthalmology of the American Medical Association. It is similar in construction to the reflecting galvanometer, a magnet, with a mirror attached, being suspended by a fiber of silk. The reflected light falls on a scale, and the deviation of this spot of light from the zero mark points to the presence of a piece of iron or steel in proximity to the magnet.

#### Gonorrhea of the Prostate.

DR. JOHN VANDER POEL, New York City, was the author of this paper. He said that in 190 dispensary and private cases this affection of the prostate was present in 39.7 per cent. An exploration of the rectum and an examination of the fluid removed by massage should be made in order to establish the diagnosis of gonorrhea of the prostate. By the proper use of the modern gonococcal remedies, such as protargol, the number of cases of prostatitis could be diminished. The treatment should be begun, if possible, within the first day or two. The anterior urethra is first washed out with a 0.25 to 0.5 per cent. solution of protargol, and then the protargol solution is injected directly into the bladder, using from 200 to 400 grams. This irrigation was best given with the patient recumbent.

#### Fractures of the Nose.

DR. JOHN O. ROE, Rochester, presented this paper. He said that the bones should be placed in good position by the introduction of a smooth sound aided by the finger externally. The nose should then be covered with a strip of adhesive plaster, and over this should be fitted a mold of aluminum or copper, and held in place by a broad strip of adhesive plaster. The internal support should consist of a spring covered with rubber, or a packing of cotton or gauze. This dressing should not be applied so as to cause pain.

DR. LEONARD WEBER, New York City, spoke of two bad cases in which he had succeeded well by the insertion of two large rubber tubes.

DR. WENDELL C. PHILLIPS, New York City, emphasized the need for all having the care of children to be informed as to the importance of carefully attending to even apparently slight injuries of the nose in these little ones. He could not agree with Dr. Roe that the external support was so much more important than the internal splint.

(To be continued.)

#### CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Dec. 11, 1901.

The President, Dr. C. Fenger, in the Chair.

#### The Conservative Treatment of Appendicitis and Fallacy of the Starvation Cure.

DR. J. H. CARSTENS, Detroit, read the above paper by invitation. He cited a case which was brought to the Harper Hospital about fifty or sixty hours after the so-called starvation method had been thoroughly tried. Patient was in collapse, almost

pulseless, and in fifteen minutes she was dead. Postmortem examination revealed a gangrenous appendix, with gangrene of the cecum around the seat of the appendix for about half an inch, with perforation. It had been walled in, but had ruptured with resulting acute sepsis. He reported two similar cases to illustrate the fallacy of the so-called starvation plan, and then called attention to the death record of the city of Detroit last year. He found 37 cases recorded as having died from appendicitis; 54 were put down as peritonitis. The death records of these 37 patients were signed by nineteen different physicians. He thought by inquiring of them he might be able to arrive at some conclusions. He received answers from twelve, who reported on 25 deaths. Fourteen of these had been subjected to operation, and 11 others died without operation. He asked these same practitioners to give the number of cases they had had during the year, and how many had died with or without operation. He received reports of 213 cases of appendicitis, of which 160 were operated during the acute attack or during the interval, in short, at any time when the surgeon thought it was proper. Of this number, 14 died. The list of surgical cases included naturally the reports of the principal surgeons, and gave a death rate of about 8 per cent., counting everything—easy interval cases, purulent peritonitis, and those actually moribund. The number of cases treated medically were 57, with 11 deaths, giving a mortality of over 20 per cent. From the reports of the physicians, in nearly every case operation had been urged, but refused by the parents of the patients, or by the patients themselves. The essayist said that he was continually hearing about the "starvation treatment" and what wonderful results are claimed for it. He thinks that it is good treatment in all kinds of bowel trouble, typhoid fever, and even appendicitis where an operation can not be done; but he emphatically protests against the starvation plan of treatment as advocated with the idea of the patient getting over the attack and then being operated on during the interval of quietude.

To sum up, the author stated that the conservative treatment of appendicitis consists in prompt operation; and that the starvation method of procrastination is vicious, and has cost many lives, because it is used as an excuse to dally with patients that should be promptly subjected to removal of the organ.

DR. WILLIAM J. MAYO, Rochester, Minn., wished he could have convictions on the subject of appendicitis that were as clear as those of the essayist. He regretted that this is not so. Unfortunately, patients do not consult the surgeon sufficiently early to be operated within the first twenty-four or forty-eight hours. He could not agree with the essayist that every case was an early one from the time the patient was seen. If a patient has been sick for five or six days, is bloated, has not been able to get a movement of the bowels, is vomiting, he knows there is considerable mortality in operating upon that class of cases at that time, and that many of them can be gotten into a more favorable condition. It could be safely said that patients who are operated upon early will nearly all get well; patients operated on at the end of the first week will nearly all get well. It is the intermediate class of cases that gives the mortality.

DR. CHRISTIAN FENGER briefly reviewed the early history of appendicitis. He believes the majority of surgeons will agree with him in saying that the severe cases should be operated on at sight. There is undoubtedly a general peritonitis existing in these, and the earlier operation is done, the better. As to the medium-severe cases, the surgeon should think, think, think, and select. It was difficult many times to do this. There must be a selection of cases, because the majority of the medium-severe cases get well without operation. He mentioned a class of cases that were half pathological and half clinical. In these the abscess was usually so located that it could be emptied through the rectum or vagina instead of waiting twenty-four hours for the subsidence of the acute symptoms.

DR. JOHN B. MURPHY mentioned the statistics of the Health Department of Chicago, saying that in 1895 there were 106 fatal cases of appendicitis; in 1896, 158; in 1897, 141; in 1898,

174; in 1899, 251; in 1900, 233; 1901 (nine months), 203 cases. He believes that the intelligence of the medical profession is far in advance of those statistics, while its practice is just what the record shows—it is not at all up to its intelligence. The question of medical or surgical treatment resolved itself into the relation of pathology to symptoms; and the relation of symptoms and pathology to time. The cases that come to the surgeon are pus cases. The profession errs in allowing patients to reach the stage of formation of pus. The diagnosis can and is made by the majority of practitioners early; by some it is made with sufficient courage to act. He believes in operating in the early stage of the disease, and by this he means inside of the first thirty-six hours, better inside of the first twenty-four hours, and there is no good reason for waiting longer.

DR. A. J. OCHSNER said that the cases reported by Dr. Carstens were improperly treated by the general practitioners. Of several hundred cases treated by him, they did not need, as a rule, more than one hypodermic injection, and not three or four hypodermic injections as mentioned by the essayist. This number of injections meant that the patients received either cathartics or food, and this in turn caused the pain. If no cathartics or food had been given, the pain would have subsided in twenty-four hours. Surgeons should operate on these cases, if possible, before the infectious material has passed out of the appendix; but in his experience the number that come under his care before this has happened is approximately 5 per cent., and in the other cases the infectious material has already passed beyond the vermiform appendix. So long as the infectious material is confined within the vermiform appendix, in any case of appendicitis, it is wise to operate, because such patients will almost invariably get well. It is not because he is afraid of operating that he selects the so-called starvation method of treatment, but it is because his mortality has only been one-fourth as high as it was before he resorted to it. Out of 198 cases in which he demonstrated a perforation at the operation, either on account of a stone or gangrene, he has had a mortality of only 9; less than 5 per cent. In every case that comes under his care within the first thirty-six hours, he invariably advises an operation. If this advice is not accepted, he is certain that there will be a mortality of almost nothing in patients who are not fed.

DR. ARTHUR D. BEVAN said that the subject had not been discussed in a judicial manner by the essayist. If he understood him, the essayist urges operation upon all cases, no matter when the patient is seen; while another speaker advocated that no case of appendicitis should be operated on except it could be demonstrated that the lesion is confined within the caliber of the appendix. Very few surgeons could demonstrate that point. The judicial remarks of Dr. Fenger, as well as the discussions of Keen and other men, would in time be generally accepted; that the mild cases should be handled in a rational, scientific way—no catharsis, cleaning out the stomach, giving opium to prevent peristalsis; that the severer cases should be operated at once; that the middle-ground cases should be dealt with in the manner indicated by Dr. Fenger.

DR. L. L. MCARTHUR stated that Dr. Bevan had expressed his own position in the matter very clearly. He made a plea for those cases that are considered moribund at the time they are seen by the surgeon, and apparently were utterly hopeless. He knew it is getting to be the practice of some surgeons to refuse to operate on this class of patients, permitting the general practitioner to shoulder the responsibility of the fatality himself. Even in such cases he believes a few of them can be saved, and of 72 cases that appeared to be moribund, in collapse, with peritonitis, he has opened in the median line, and has saved 19, but he had operated 17 consecutive times before he got one patient to live. He feels, therefore, that even in utterly and apparently hopeless cases something should be done for them.

DR. FERNAND HENROTIN had not reached the point where he could lay down rules for his guidance in cases of appendicitis. He took it for granted that very few surgeons operated on patients who were moribund. On the other hand, they did not

operate on patients who were practically well. If patients recovered from the acute stage and were then seen if operated in the interval, there was practically no danger. The important thing was to emphasize that appendicitis is a surgical disease. If the case can be seen early, when it is presumable that the infection is still confined within the appendix, nothing is more gratifying than when the appendix is removed. That class of patients usually recovered.

DR. E. WYLLYS ANDREWS stated that he knew from practical experience that the conservative treatment, including early washing out of the stomach and withholding of cathartics, is followed by death in many instances. He had a patient in whom he carried out this treatment rigorously; but the patient died between his evening and morning visit. He did not think there was any fault in the execution of the conservative technique. He cited a similar case that terminated fatally in his own practice, as well as cases in the practice of others. He knew of cases seen by Dr. Ochsner in consultation that have died without operation. He thought it was folly to permit the statement to go out that a large number of cases can be saved by conservative measures and contrast that method on the one hand with the results of operative treatment on the other.

DR. A. H. FERGUSON said that surgeons were all agreed that in the severe cases, where there is no doubt as to the diagnosis, and there is tumefaction, with all the other symptoms of acute inflammation of the appendix, the appendix ought to be removed as soon as possible. Statistics show that that is the best treatment. In a large percentage of cases, surgeons operated as soon as they could, whether the patients were apparently moribund or not, because they felt it a duty to the patients; they felt that they were not cowards if they gave patients the chance of an operation, even though that chance be very little. He had lost two patients who were operated on within forty-eight hours after the onset of the attack. So far as he could judge, he managed his cases after the method mentioned by Dr. Mayo, although he was prepared to operate more frequently upon the intermediate cases than he did formerly, because he felt that a patient would die now and then because he did not operate.

DR. D. W. GRAHAM said that he did not like to hear anyone lay down rules for the treatment of appendicitis. Every operator had his own method and made his own rules. In short, a surgeon would make a rule to-day and violate it to-morrow. He had been operating on the intermediate cases more frequently than he did formerly. He believed that more patients could be saved who would otherwise die by simply having regard for a general surgical principle, namely, the relief of surgical tension. All that some of these cases required was a simple incision and drainage for the time-being. The appendix could be removed at a subsequent operation, if deemed necessary.

DR. A. GOLDSPOHN had applied the method of Dr. Ochsner in three very mild cases. The symptoms were not marked, but the tenderness was positive. He had also had patients brought at once to the hospital so as to be able to do surgery at any moment, and then instituted the starvation treatment. Two of the three very mild cases that he thought would have recovered at home without almost any medical treatment, that had not been overfed, did very well, but the other case did not. This patient was operated on, and a recovery obtained, although he had a good deal more serious case to deal with than he would have had if he had operated twenty-four hours earlier.

DR. WILLIAM M. HAERSHA said there was no question as to the treatment of severe cases at the start, if the surgeon saw them; but the surgeon saw the majority of the cases after two or three days. He had held for several years the view advocated mostly by Richardson, of Boston, that it was dangerous at this stage to operate on every case. He still thought so. He believed there were cases in which the treatment advocated by Dr. Ochsner was the very best that could be pursued. He maintained that every case should be operated on that was progressive at the end of thirty-six hours.

DR. A. I. BOUFFLEUR was inclined to follow the course outlined by Drs. Mayo and Bevan, with the general proposition

that he would operate when in doubt. At the present time that was the most comforting position which he was able to occupy, and such being the case, he adopted it as the nearest thing to a rule that he could make.

DR. EDWARD H. LEE said there was one form of appendicitis that had not been mentioned, namely, that form of the disease designated as streptococcus infection, the infection taking place through the wall of the appendix without perforation. It could not be termed a general suppurative peritonitis; but postmortem examination would reveal distention of the entire intestinal tract, a hyperemic condition of the intestine without suppuration. The appendix might or might not show some gangrene. As a rule, it did not show any gangrene whatever. In these cases the symptoms were aggravated from the start; vomiting was persistent; there was no localized tenderness, so that it was very difficult to make an accurate diagnosis of appendicitis. These cases terminated fatally in twenty-four to forty-eight hours, and surgical or medical treatment would not be of any value whatever. However, these cases were very rare.

#### NORTH BRANCH OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Regular Meeting, held Jan. 16, 1902.*

The President, Dr. A. M. Eaton, in the Chair.

#### Diagnostic Value of Digital Examination in Diseases of Rectum.

DR. H. A. BRAY dwelt at some length on the fact that the general practitioner treats diseases of the rectum too much from a symptomatic standpoint and without making a local examination of the part affected. Cases of this character usually present symptoms of extreme nervousness, melancholia, sometimes with suicidal intent, pain in the rectum, digestive disturbance, disorders of the liver, etc., and very often the case is treated for the most prominent of these symptoms without the real cause of the trouble being suspected. Several cases were cited in support of this theory; in one of them the patient had been treated by many physicians for constipation, the condition having existed many years. When he came under the author's observation a digital examination was made which revealed a stricture  $2\frac{1}{2}$  inches above the external sphincter muscle. In another case which was being treated symptomatically for constipation, local examination revealed carcinoma of the rectum situated 2 inches above the external sphincter muscle. The method of making the examination was given in detail and especial stress was laid upon the importance of examining the parts close to the anus, as well as those higher up in the bowel, and the opinion was expressed that practically all pathologic changes in this region except internal hemorrhoids can be detected in this manner.

#### Operative Treatment of Hemorrhoids.

DR. CHARLES F. NASSAU read this paper. The different methods of procedure in operating on this condition were fully discussed and the view expressed that the ideal method of operating is to treat the hemorrhoidal area in the same manner as you would treat a varicose condition in any part of the body, thus avoiding the pain produced from unhealed ulcerating surfaces, the result of sloughing away of ligatures or the granulating lines left by the clamp and cautery. As regards the use of escharotic injections they were considered as of no use in external piles and although producing considerable benefit in some cases of internal hemorrhoids, the dangers attendant upon their application were such as to overbalance their merits. Local infiltration anesthesia was recommended in suitable cases, although it was thought to increase the technical difficulties of the operation. In cases having comparatively small internal hemorrhoids, stretching of the sphincter and careful attention to the fissures, such as the application of the cautery, division of the base to healthy tissue or complete excision followed by careful suture were recommended. In minor cases of isolated external piles excision of the veins involved followed by careful suturing of the

skin wound was recommended. The Whitehead operation, while based upon correct grounds, was considered at fault in its technical details, and as it is also sometimes followed by stricture and even incontinence, it was not advised. For the more difficult cases the excision of the entire pile-bearing area followed by suturing was thought to be the most desirable procedure. This operation can be done either under local anesthesia or ether, according to the indications of the particular case. Considerable stress was laid upon the importance of general and personal hygiene following this treatment and especially should the patient be instructed to secure a daily action of the bowels.

#### Diagnosis and Treatment of Carcinoma of Rectum.

DR. GEORGE C. ROSS considered that there are five varieties of this condition: epithelioma, scirrhus, encephaloid, colloid, and melanotic carcinoma or sarcoma, the frequency of their occurrence being in the order named. The most common form of cancer of the rectum is the variety of epithelioma known as adenocarcinoma. The most rapidly fatal form is the sarcoma or melanotic carcinoma, which is also the most rare, only 11 cases of this variety being so far recorded. The importance of both digital and optical examination in all cases of local ailment of the rectum was emphasized and the author considers that in cases of doubt the administration of a local anesthetic, or even ether, if the case indicates, is not only permissible but demanded, when necessary, in order to secure a specimen of the growth for microscopic examination. Cancer more frequently occurs in old age, the percentage of cases increasing very rapidly after the age of 20. Attention was directed to the fact that the history of the case will often be of material aid in making a diagnosis of the condition, some of the most common symptoms being loss of weight and strength, cachexia, and difficult defecation, the stools containing bloody, mucous discharges.

Statistics regarding the immediate mortality rate were given and it was shown that about 20 to 30 per cent. of the cases are immediately fatal when radical measures are employed, the causes of death being peritonitis, shock and retroperitoneal infection, with resulting septicemia. There are very few reported cases where the patients have remained perfectly well for a period of four years, and the best authorities on this subject seem to give a very unfavorable prognosis. The two principal methods used for extirpation of the diseased rectum are Krasko's operation and its modifications, and one which is applicable in the female, using the route of the perineum to gain access to the bowel. This operation is claimed by those who have used it to be a very satisfactory one. In the cases where radical treatment is not indicated, either from the disease being too far advanced or for any other reason, colostomy is the only alternative, and this operation was also recommended in some instances as a preparatory measure in order to allow the patient to build up his strength before undertaking radical procedure.

DR. WILLIAM L. RODMAN, in discussion, stated that he considered too much stress could not be laid upon the importance of a thorough digital examination in diseases of the rectum. In regard to the different varieties of carcinoma he considers the adenocarcinoma of the rectum of the most common occurrence, and in his experience the scirrhus and encephaloid forms of the disease have been rare. Several instances were noted of cases which had come under his observation, where in opposition to the usual rule that carcinoma of the rectum usually proves rapidly fatal, five, ten or even twelve to fifteen years had elapsed before death, the patient in the interim remaining in fairly good general condition. If radical procedure is to be undertaken the importance of early operation was urged, and when the disease has become far advanced before surgical relief is sought colostomy is thought to be the most advisable measure, as at this time only palliation can be hoped for, and this operation seems to afford more relief than any other.

The different operations in use for the removal of hemorrhoids was carefully considered and the Doctor stated that after more or less experience with all of these he feels that ligation is to be preferred. The Whitehead operation was making a

major procedure out of what should be a minor one. The author stated that he had known excellent results to follow carbolic acid injections, but felt that the untoward results sometimes following this method more than overbalanced its merit. Regarding the clamp and cautery the chief objections seemed to be the liability of hemorrhage following the operation when the stump is cut off too close, and in some instances embolism has occurred, followed by sudden death. With the ligature operation, the hemorrhage, if it occurs at all, usually happens before the patient comes from under the influence of the anesthetic and no instances have come under his observation where secondary hemorrhage has occurred.

DR. A. H. HULSHIZER felt that the operation which each individual was most familiar with would give the most satisfactory results, for the reason that it would be performed in a more skilful manner, and stated that in his own experience in cases where the ligature had been used, which is the method he prefers, there had been little or no complications.

DR. E. W. HOLMES urged the necessity for thorough local examination in all cases of rectal diseases, and cited instances where, under mistaken diagnosis, due to the physician relying wholly upon the clinical conditions present, grave errors had been made in treatment, and relief by operation delayed until it was too late. Reference was made to an electric proctoscope which had been recently placed on the market which seemed to be a very valuable instrument.

DR. G. BETTON MASSEY discussed at some length the different varieties of cancer and the various methods employed in their treatment and from his own experience is inclined to favor the electric cautery. In two cases which have recently come under his observation he has used this method with very satisfactory results. He especially urged the early recognition and treatment of this condition.

DR. MORDECAI PRICE said that the different operations performed by different surgeons for rectal disorders is due principally to the individual's familiarity with some particular operation. Formerly he was much in favor of the Whitehead operation, but some years ago saw a case in which the after-results were such as to deter him from practicing it further. Since that time he has been using the clamp and cautery, and he has never experienced any untoward results therewith. Regarding carcinoma of the rectum he is of the belief that there are very few, if any cases in which it can be cured.

DR. LEWIS H. ADLER considered that, notwithstanding the fact many surgeons are opposed to operating on hemorrhoids when they are in an inflamed condition, it is better to operate at this time than to wait until the disease has made such progress that the patient is greatly weakened thereby, which will be the result in a majority of the cases, owing to the fact that when the patient is not suffering pain from the piles, he will not consent to an operation. Stress was laid upon the importance of differential diagnosis between external and internal piles, and for the relief of the external variety the thermo-cautery was recommended. He considered the clamp and cautery as superior to the ligature and believed that when this method is properly used the danger is practically nil.

DR. ANDREW J. DOWNES considered that one of the most essential points was to be sure not to include the skin in either the clamp or ligature, as he thought that this was responsible for much of the pain following either method. For the purpose of controlling hemorrhage, instead of the ligature, he recommends the electro-hemostatic forceps.

#### SAN FRANCISCO COUNTY MEDICAL SOCIETY.

*Monthly Meeting, held Jan. 14, 1902.*

Dr. John C. Spencer, in the Chair.

#### A Brief Resume of the Present Aspect of Scleroderma.

DR. A. B. GROSSE read this paper. After a review of the etiology, course and clinical aspect of the disease, he presented a case, one of seventeen which he had the fortune to observe, and the second only which had been reported in San Francisco, the first having been reported by Dr. Leo Newmark in 1892. C. W., male, aged 51, nativity Schleswig-Holstein; porter, mar-

ried, presented himself March 25, 1901. He had had gonorrhea, stricture, epididymitis and chancre not followed by secondaries—all over 25 years ago. About 12 years ago he noticed swelling, rigidity and formication of skin and muscles of both hands, later encroaching on half the forearm. Symptoms were especially noticeable on days he did not work. At present time skin of fingers was thin and parchment-like, muscles rigid, fingers flexed, neuralgic pains in hands and forearms; impaired motor function makes him useless for his occupation. Skin of face was affected from chin to a line through outer canthi of both eyes. Mucous membrane of mouth was affected, scalp indurated, also feet, upper half of legs and lower half of thighs edematous.

August 25, 1901: Forehead becoming affected; hands and forearms in stage of atrophy, lower half of thighs to toes, stage of infiltration; bands of sclerodermic patches on abdomen and chest; paroxysms of sweating; complaints of cold; general pigmentation, but much lighter than Addison's. Nov. 11, 1901: Skin symptoms are progressive; he complains bitterly of sensation of cold; formication and shooting pains in finger tips and unbearable neuralgia of extremities and joints. Dec. 26, 1901: Skin lesions have progressed rapidly; skin is tigh over bony prominences and very painful; pigmentation well marked; perspiration now only of feet and legs. Jan. 9, 1902: Right side of body is much more involved; marked loss of function and deformity of right hand and paretic condition of right side of face; he can not chew food; sense of taste is impaired; complains of seeing double; he has not perspired for one week. Jan. 13, 1902: Definite change for worse since last visit; shooting pains through chest and down lumbar spine; breathing and performance of necessary motions are difficult; clonic contraction of muscles of both hands.

#### Four Cases of Puerperal Toxemia Treated by Accouchement Force.

Dr. J. F. McCoxe read this paper. He said that opinion was divided as to the expediency of manual dilatation and incision of the cervix uteri with rapid emptying of the uterus in cases of eclampsia, and as these were comparatively new methods of treatment and there were few statistics as to results he reported the following cases of extreme puerperal toxemia:

CASE 1.—Mrs. F., primipara; aged 22; previous history negative; date of expected confinement, Feb. 26, 1900. On Nov. 1, 1899, urine was examined, no albumin, urea 2 per cent., no upward symptoms. On Nov. 10, headache and tingling existed in left ring finger. On Nov. 11, 9 a. m., eyelids were swollen, face disfigured, hands pale and swollen, ankles swollen and feet shapeless; she had severe frontal headache and dimness of vision. Patient was removed to hospital. In ambulance first convulsion occurred so severe that lower jaw was dislocated on both sides. She arrived at hospital unconscious, pulse weak and rapid, breathing short and shallow. Cervix was cut laterally and a five and one-half months' fetus rapidly extracted; placenta was removed and uterine bleeding encouraged by abdominal poultices and warm douches. There were two subsequent convulsions; 150 c.c. of urine were excreted the first day. In six weeks urine was normal and patient in good health.

CASE 2.—Mrs. V., aged 39; ten years ago, after pernicious vomiting, swelling of face and extremities, aborted a 3 months' fetus. Feb. 24, 1900, she was six months pregnant; conditions were normal. April 21, amount of urine decreased and albumin present. Milk diet was ordered, purgatives, diuretics and diaphoretics were given. May 1, she had a short convulsion; 50 c.c. of bloody urine were passed in 24 hours. She was removed to hospital. May 2, there was general edema, dulness of sight and intellect, and epigastric pain. Nitroglycerin, salines and hot-air baths were ordered. Urine increased, albumin lessened, patient remaining stupid. May 5, she had a second convulsion; accouchement force was decided upon. Third convulsion occurred before operation; patient was deeply cyanosed, pulse rapid and weak, with respiration labored. We delivered fetus, dead several days. There was no further convulsion; recovery uneventful.

CASE 3.—Mrs. S., aged 44, four children, pregnancies normal. Last menstruation was April, 1901. She came under care Sept. 13, 1901, suffering from constant nausea and severe frontal headaches. Blindness occurred following gradual loss of vision for two weeks past. She had been on milk diet, salines and nitroglycerin under the care of country physician. Sept. 15, she was restless; sightless eyes, edema of face and extremities; mind much disturbed, persistent vomiting, epigastric pain; temperature was 96, pulse 98. She was placed on milk diet, nitroglycerin hypodermically, hot-air baths and high enemata of normal salt solution. Sept. 16, amount of urine was 150 c.c. Maniacal tendencies existed; vomiting uncontrollable. Manual dilatation of cervix and version were made; dead fetus delivered. Two hours after operation vomiting had stopped, but violent mania ensued lasting for thirty hours, when it suddenly subsided. Amount of urine became very great, passing 3000 c.c. on the fourth day. Sight improved and in three weeks patient recovered.

CASE 4.—Mrs. B., primipara, aged 23, previous history good. Nov. 23, 1901, she entered hospital seven months pregnant; suffering with nausea and vomiting for two weeks past, headache and epigastric pains and general edema. She passed urine 400 c.c. in 24 hours, urea 10 gms., albumin 1.8 gms. Patient was put on mag. sulph., infusion digitalis, milk diet and hot baths. Nov. 26, urine amounted to 350 c.c. Nov. 27, 1 p. m., she had a convulsion lasting twenty minutes; patient remaining cyanosed, respiration labored, pupils contracted. Chloral was given by rectum. At 4:10 p. m. she had severe convulsion. At 4:30 p. m. manual dilatation and multiple incisions of cervix were made, forceps applied and seven months' child delivered alive. There were no further convulsions; gradual increase of urine and decrease of albumin. Dec. 14, mother and child left hospital in good health.

In Cases 2 and 3 the fetuses were dead, refuting the statement often made in text-books that convulsions ceased when fetus perished. Urine charts showed a progressive decrease in the albumin and increase in urea after the operation in Cases 1 and 2, but in Cases 3 and 4 the albumin decreased, the amount of urine increased, but amount of urea bore no constant relation to condition of patients.

#### On Some Surgical Affections of the Parotid Gland.

Dr. EMMET RIXFORD read this paper. He said that because of its peculiar anatomic relations the parotid gland was of extraordinary surgical interest, from a pathologic standpoint, on account of the great number of surgical affections to which it is subject; and from an operative standpoint, on account of its proximity to important structures, its transmission of important nerves and vessels and the peculiar properties of its secretion. The lymphatic glands of the parotid were all situated within the capsule or fascial sheath of the gland consisting of a superficial and a deep set, and receiving, as they do, lymphatics from wide regions so prone to infections as the eyelids, the external ear, the auditory meatus and the posterior nares, explained many cases of suppurative processes in the parotid region. The excretory duct opening directly into the mouth was considered the most frequent transmitter of pyogenic bacteria into the parotid, probably accounted for by diminished secretion of saliva in fevers, e. g., typhoid, pneumonia, cholera, etc., and after large abdominal operations. In dispensary practice an eczema of the ear with a painful swelling over the parotid was a common thing. The sheath of the parotid mingling with the periosteum of the ramus at its posterior border pus might reach the parotid by direct extension from an osteomyelitis or periostitis of the lower jaw. When pus was superficial incision was without risk to facial nerve or earotid, but when deep it was far safer to incise only deeply enough to open fascia over the gland and then use blunt dissection. If deep incision was necessary it should be parallel to facial nerve. Cavernous angioma rarely occurred in the salivary glands, although common just beneath the skin of face. An ordinary subcutaneous angioma in the parotid region was not properly an angioma of the parotid gland and diagnosis as such should be made only when the

microscope showed gland tissue between its lobules. In a baby one year old he had removed a true angioma penetrating deeply into the parotid, which was shelled out with comparatively little difficulty. Opening into the gland was  $2\frac{1}{2}$  cm. in diameter and exposed the branching facial nerve crossing the floor of the opening. Primary union resulted with very slight scarring. The so-called mixed tumor was benign, at least in the beginning, often lasting 8 or 10 years before becoming large enough to lead the patient to undergo operation. It was among the more frequent tumors of the parotid and might contain cartilage in varying amounts. He cited case of a woman, age 35, with tumor of the parotid; hard, nodular, the size of a man's fist. First noticed 4 years before. Tumor extended down to level of hyoid bone. Facial nerve was displaced downward 6 or 7 cm. below normal situation lying in groove between two large nodules of the tumor. Wound closed with primary union and recovery. Sarcoma as a primary tumor of the parotid was rare and might be of any one of the ordinary forms of sarcomata and might be encapsulated, a fact of enormous value in prognosis. He reported a case of removal of encapsulated sarcoma together with entire parotid gland one year ago with no sign of recurrence at the present time. In two cases of epithelioma of the cheek the inner end of Stenson's duct was removed and communication of the remainder with mouth established. In first case 2 cm. of the duct were taken away, a funnel of mucous membrane was drawn into the wound and fastened to the anterior edge of the masseter muscle, and the end of the duct introduced through its apex and secured with fine silk sutures. Union resulted with no leakage of saliva through wound. The dimple on inner side of cheek caused no difficulty in mastication or from food lodging in it. In the second case excision of nodule required cutting directly through the whole cheek, making an opening 6 cm. in diameter which was sutured antero-posteriorly in order not to limit the action of the lower jaw; 3 cm. of the duct had been removed. A strip of mucous membrane 5 mm. wide was dissected from the edge of the inner wound and brought out around the edge of masseter and united to the remnant of the duct with fine silk suture. Union occurred without suppuration in wound in cheek, and the new duct remained open and could be entered with a fine probe.

#### NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, held Jan. 16, 1902.*

The Vice-President, Dr. George L. Peabody, in the Chair.

#### The Food Factor as a Cause of Health and Disease During Childhood.

DR. JOSEPH E. WINTERS pointed out the paucity in milk of iron, and that while the infant begins life with a store of iron in the liver and other parts of the body, this iron is gradually used up, so that by the time the weaning time arrives the system is in need of a new supply of iron. For this reason, late weaning or the too prolonged use of an exclusively milk diet will cause anemia. Oatmeal was found to be rich in the constituents necessary for the proper growth and development of the child at this period of life, iron not excepted. It was, however, indigestible unless the cellulose were removed by cooking and straining. It was not prudent to change to cereals in the heated term, and it was often well to substitute barley at this season of the year. A child of 15 months should be allowed a crust of stale bread twice a day, and should be given also whole milk, oatmeal or barley jelly, and a soft-boiled or poached egg two or three times a week. It should be remembered that in the growing child carbohydrates were necessary in order to meet the large demand for energy and at the same time shield the proteids and fats from oxidation so that they may be stored for future needs. Nitrogenous matter is essential to every vital process, and proteids must be supplied to the growing child not only for the building up of the muscles but for the proper growth of other structures. Unlike the adult, the child required a generous supply of mineral salts with which to build up the osseous system, but in order that they may be properly assimilated it is absolutely neces-

sary that they remain as in nature in organic combination. An abundance of fat should be the main characteristic of the diet of the young child. The relatively large heat-radiating surface in the child called for an adequate supply of heat, and this was best secured by an ample supply of fat in the food. If the latter were deficient in fat, rickets would result. There was no apparent difference in the nutritive value of animal and vegetable proteid, and the latter possessed the advantage that it is free from crystalline extractives which exist in meats in the proportion of 15 per cent. Metabolism was especially active in the growing child, and an excess of animal food, by over-stimulating this metabolism, would interfere with the laying on of fat and of muscular flesh. One of the greatest evils of a meat diet was that it usually created in the child a distaste for cereals, vegetables and milk—in short, acted very much like coffee, tea and alcoholic beverages. The importance of having a due proportion of the alkaline carbonates in the food might be inferred from the fact that an alkaline fluid was essential to the proper functioning of the body cells. These alkaline bases were to be found in organic combination in certain vegetables and cereals. Vegetable food was probably the chief factor in the production of the coloring matter of the blood. Dr. Winters made strenuous objection to the present tendency to teach that beef and beef juice should form a prominent part of the diet of very young children. He declared that there was more so-called rheumatism, anemia, valvular disease of the heart and chorea in children at the present time as a result of this too free use of meat in the diet of young children than from any other cause. Meat juice should not be given until the age of three years, and then only sparingly.

DR. LEROY M. YALE said that his experience had led him to practically the same conclusions. The children of the poor, by their free outdoor life, had an opportunity to offset in a measure these defects of the diet, but not so the children of the rich, who in their staid constitutions had no chance to exercise freely; hence, the latter were often the victims of rheumatism and gout.

DR. JOHN DORNING thought the reader of the paper had done a good service in calling attention to the dangers of using beef juice too freely in the diet of young children. It was not rare to find an infant of three months receiving from half an ounce to one ounce and a half of beef juice daily. Milk and cereals should be the chief articles of diet, and he would place oatmeal at the head of the list for both children and adults. He preferred to give the children whole-wheat bread.

DR. THOMAS S. SOUTHWORTH said that the transition from an exclusively milk diet to a mixed diet was a critical period, and without adequate and enlightened medical supervision the child was apt to lay the foundation for much ill health. He hardly felt, however, like agreeing with Dr. Winters in such a wholesale condemnation of beef juice for young children, though admitting that if given in too large quantity it was deleterious. He felt sure that it was often valuable, not only as a nutrient but as a means of improving the quality of the blood.

DR. ELMER LEE was of the opinion that only such food as was in itself capable of germination was suitable for either the child or the adult. Meat was not only costly, as compared with cereals, but was of low nutritive value.

DR. WINTERS, in closing, declared that many of the proprietary infant foods in the market were devoid of any nutritive value by reason of the chemical process to which they had been subjected in order to preserve them. The milk with which they were given to the child, and not the so-called food, was really to be credited with any good resulting from their use. In his experience, the children of the well-to-do in this city were unable, as a rule, to take whole-wheat or other coarse bread without digestive derangement, as he had many times proved to his own satisfaction by watching the digestive trouble disappear simply by forbidding the use of such bread. He would guarantee that an anemic child, free from organic disease and from infection, if given milk, cereals and vegetables in proper proportions would, in every instance, become rosy and rotund.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, XII.

(Continued from page 347.)

#### Methods of Administration—Continued.

Local applications of medicines may be employed on mucous membranes as well as on the skin; and when applied to other surfaces than the skin aqueous solutions, washes and gargles may be used.

When drugs are applied to the skin in order to produce general systemic effect it is usually in those cases in which the stomach has to be protected for certain reasons and where hypodermic medication can not be judiciously resorted to. Difficulties may sometimes arise in calculating accurately the dose of the preparation used, on account of the uncertainty of absorption.

#### Endermic Administration of Drugs.

This method consists in producing a raw surface by means of a blister, which will readily absorb the medicinal substance, such as strychnin, morphin, atropin, or quinin. This method was formerly employed, but is practically obsolete, being superseded by hypodermic medication.

#### The Use of Liniments.

Liniments are less used than formerly. Their value probably does not consist in the properties of the ingredients they contain so much as in the vigor of the rubbing or massage of the parts to which they are applied. Their effects are purely local. In the application of liniments mistakes are often made by saturating the bandage with a liniment containing one of the volatile preparations, thus producing a large blister or possibly sloughing. The following are the official liniments: Linimentum ammoniæ (volatile); linimentum belladonnæ; linimentum calcei; linimentum camphoræ; linimentum chloroformi; linimentum saponis; linimentum sinapis comp.; linimentum terebinthinæ. The strength of these liniments range from 10 to 20 per cent.

#### Ointments.

Some drugs, if properly mixed with certain fatty substances as a vehicle, will be absorbed through the skin. In this manner mercury can be given and will be absorbed, if well rubbed in, without any abrasion of the skin. Quinin is often administered to children by this method. It can be mixed with lanolin, which is the best vehicle for such purposes. The selective points for application are the axillary spaces, and the inner side of the thighs and groins. Mercurial inunctions may be rubbed in between the scapulae.

In some of the venereal clinics of Europe patients with bared backs are daily placed astride a long plank, one in front of the other; each one is engaged in rubbing a definite amount of the mercurial ointment into the skin of the patient immediately in front of him.

Oleates are supposed to be absorbed more readily than other ointments. There are three official oleates: oleatum hydrargyri, oleatum veratinae and oleatum zinci.

#### Suppositories.

Drugs are sometimes administered by the urethra, vagina or rectum, either for local or systemic effects. When introduced in the form of a suppository, oil of theobroma is most frequently used as the base, as it melts at the temperature of the body and remains as a solid at the ordinary temperature outside the body.

The following rules are generally observed in making the different forms of suppositories: Rectal suppositories should be cone-shaped and of about one gram in weight (15 grains).

Urethral suppositories should be cylindrical or pencil-shaped and weigh about one gram. Vaginal suppositories should be globular in shape and weigh about three grams. Suppositories for children should be proportioned accordingly. Glycerin is sometimes used as a vehicle, being substituted for cocoa-butter.

(To be continued.)

#### To Remove Dandruff.

According to *Merk's Report*, among the remedies which have been found to be most serviceable in the treatment of dandruff are resorein, tannoform, salicylic acid and boric acid. The following mixture is recommended as being most efficacious:

|                        |       |      |
|------------------------|-------|------|
| R. Resorein .....      | 3i    | 3 75 |
| Tannoform .....        | 3i    | 3 75 |
| Acidi salicylici ..... | gr. v | 32   |

Misce. Dissolve the powder in three ounces of alcohol and one ounce of water and filter. Sig.: Apply locally to the scalp.

Or:

|                    |     |      |
|--------------------|-----|------|
| R. Resorein .....  | 3i  | 3 75 |
| Acidi borici ..... | 3ss | 1 90 |
| Aquæ .....         | 3iv | 120  |

M. Sig.: Apply locally to the scalp.

The foregoing ingredients may be incorporated with an ointment if desired, such as aquæ unguentum rosæ (cold cream), adeps lanae hydrosus, petrolatum, etc.

#### Treatment of Bronchitis with Bronchoplegia.

Martinet, as noted in *Med. News*, states that in treating bronchitis the two general indications are to lessen the cough and diminish the bronchial secretion. But a third indication, sometimes of great importance, is to combat bronchoplegia, the paralysis of the smooth muscles of the bronchi. This may be due to the toxins of certain infectious diseases, diphtheria, influenza, etc., or may be produced by mechanical causes in the course of chronic bronchitis. There is gradual progressive dyspnea with ineffectual cough, accumulation of secretions and congestion. In such a condition an opiate or sedative might do harm. Drugs that will stimulate the nervous system and reawaken the bronchial contractility are required. A cardiotonic and hemostatic pill of value is:

|                         |          |      |
|-------------------------|----------|------|
| R. Ext. hyoseyami ..... | gr. v    | 30   |
| Quinina sulph. ....     | gr. xxiv | 1 50 |
| Ergotin .....           | gr. xlv  | 3    |

M. ft. pilulae No. xxx. Sig.: Six or eight pills daily.

Renaut's treatment of bronchitis is to give balsams, such as terpin, syrup tolutani or Canada balsam for the first three or four days; then for as long a time he gives ergotin combined with opium or hyoseyanus as a suppository. At the same time he prescribes the following pills:

|                         |          |      |
|-------------------------|----------|------|
| R. Ext. hyoseyami ..... | gr. v    | 30   |
| Terpin .....            | gr. xlv  | 3    |
| Ergotin .....           | gr. xxiv | 1 50 |

M. ft. pil. No. xxx. Sig.: One pill three times a day.

In bronchoplegia accompanying la grippe he regards strychnin as the most useful remedy, as follows:

|                           |          |      |
|---------------------------|----------|------|
| R. Strychnina sulph. .... | gr. ss   | 03   |
| Ergotin .....             | gr. xxiv | 1 50 |
| Quinina sulph. ....       | gr. xlv  | 3    |

M. ft. pil. No. xxx. Sig.: Take one pill every two hours with a hot infusion sweetened with syrupus tolutani and containing a teaspoonful of old brandy.

#### Formalin in Glycerin.

Jordan, in the London *Lancet*, has found that by combining formalin with glycerin the irritating nature of the drug and the pain which it causes may be prevented. Applied to the throat with a brush, a single application can be depended on to kill every micro-organism with which it comes in contact. In follicular tonsillitis formalin in glycerin in strength of 2 to 4 per cent. is a specific if used before there is a deep collection of pus. After a single thorough application the temperature falls to normal within a few hours and remains normal. The application is usually attended by a little soreness, lasting only

a few hours. Formalin in glycerin is useful in all parasitic skin diseases, especially in tinea tonsurans. The entire area is cleansed with soft soap and water and a 4 per cent. solution of formalin in glycerin is applied.

#### Sodium Citrate in Diabetes.

Sodium citrate has been recommended by Dálché and Cartaret, in *Bull. Gén. de Thév.*, as a valuable preparation in aiding in the reduction of the excretion of sugar. It is said not to disturb the stomach; for, by its decomposition in the stomach, free citric acid is set free and is well borne.

#### Gasoline Poisoning.

A subscriber sends us the following: "Having witnessed a nearly fatal case from swallowing gasoline and water kindly inform me what this liquid is chemically, and what the antidote is, if any. The results in this case were marked pallor, cyanosis, almost imperceptible pulse, pin-point pupils, sleepy and stupid state (requiring continued stimulation mostly of strong hot coffee) following the first condition of strangling, spasmodic croup, and vertigo."

Gasoline, like benzine, rhigolene, kerosene, paraffin, and many lubricating oils, is obtained from crude petroleum, and is a mixture of hydrocarbons, though mainly of the methane series, the formulas of the latter being in the order  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_3\text{H}_8$ , etc. It may be classified as an intoxicant and gastro-intestinal irritant, along with other members of the hydrocarbon group, such as alcohol, ether, chloroform, chloral, and even turpentine. Its effects, therefore, are very similar to alcohol. The patient in this case probably passed through some of the stages similarly produced by alcohol, namely, the stages of stimulation, narcotism, anesthesia, not reaching the last or paralytic stage. The antidotal treatment, therefore, should be similar to that for the other anesthetics.

T. Sollmann, in his valuable text-book of Pharmacology, commenting on the use of gasoline as an anesthetic, states that toxic effects obtained in animals from too concentrated gasoline vapor consist primarily in very characteristic convulsions. The animal struggles violently, then falls on its side and claws the air with all fours, as if running; the pupils are widely dilated; reflexes are absent. The spasms are intermittent, and between them the subject is limp, except that the toes and eyelids continue to twitch. The respiration is first stimulated and then weakened. There is a paralysis of the vagus, then depression of the cardiac muscle and later of the vasomotor center. Either heart or respiration may stop first.

### Medicolegal.

**Circumstantial Evidence in Abortion Case.**—The Supreme Court of Indiana holds, in *Diehl vs. State*, that the absence of the necessity for producing an abortion in order to save the life of the mother may be shown by circumstantial evidence in prosecutions for alleged criminal abortion.

**Can Not Employ Physician for Smallpox Patients.**—The Supreme Court of Idaho holds, in the case of *Castle vs. Banock County*, that an individual member of the board of county commissioners can not employ a physician to care for smallpox patients at the expense of the county. Referring to a number of cases, from Indiana and other states, that were cited here, the court says that it will be observed, by reading them, that the board of county commissioners, or the city council of a city, are empowered to do certain things; but nowhere does it find in the citations that an individual member of the board of county commissioners, or a member of a city council can make a contract and thereby create an obligation binding upon the county or city. Of the duty of the officers to act promptly, and take all necessary steps to check the disease, when smallpox was found in the county, the court says that there could be no question. But, it goes on to point out, it did not appear from the record that a board of health was organized, or that any effort was made by any one in behalf of the city or county, excepting that the chairman of the board of county commissioners told the physician suing to look after smallpox patients,

and that the county would pay him for his services. The record did not disclose any authority in the chairman to make this or any contract on behalf of the county. The law provides a clerk for the board of county commissioners, whose duty requires him to keep a record of all proceedings of the board. This is a public record, and all parties dealing with the county are charged with notice of this record. The physician suing could have informed himself of the authority the chairman had to make this contract, either as chairman of the board of county commissioners or as a member of the board of health (if there had been one), by an examination of the record, and, the court holds, it was his duty to do so before he accepted the employment. If he accepted such employment from the chairman, it was voluntary on his part, and he could not recover for such services.

**Medical Treatment of Stowaway.**—The United States District Court says, in the case of the *Laura Madsen*, that it is a principle of maritime law that a ship is liable for the necessary medical treatment and expenses incident to the cure of seamen who become ill or suffer injuries in its service. But in this case the man who was injured had imposed himself on the vessel. He was a stowaway, who was discovered when the vessel was one day at sea. He was not a sailor, but the captain required him to sign the shipping articles to serve as a member of the crew to the end of the voyage and he was marked on the articles as a stowaway. He was not required to do a seaman's work, but was willing to lend a hand whenever he found an opportunity, and while he was voluntarily hauling on the braces when the vessel was being maneuvered he fell on the deck, and was severely injured. On arrival in port, the physicians seeking in this case to recover for his medical treatment removed him to the hospital, and treated his injuries until he was practically cured. Whether the captain induced them to undertake the cure of the stowaway by promising that the ship would be responsible for their bill, was in dispute. According to the opinion of the court, however, it was immaterial whether there was such a promise by the captain or not. It says that neither the vessel, her owners, nor master owed the man any duty, except to give him humane treatment while he necessarily remained on board. He came to the port as a waif from the sea, helpless and destitute, and having no claim upon any particular individual, and was necessarily a public charge, or an object of private charity. The captain of the ship was not authorized to pledge the ship for the expense of his cure or maintenance as an act of charity. The authority of the captain of a ship to pledge the credit of the ship is limited by necessity. He has no authority to enter into any contract which can be enforced by a suit against the ship not required to make his ship seaworthy, or to meet her obligations as a carrier or to her crew. The act of signing the shipping articles at sea under compulsion did not attach the stowaway to the vessel, nor create any obligation different from what necessarily arose from the fact of his being on board by his own voluntary and wrongful act. Wherefore, the court dismisses the suit of the physicians, at their cost.

**Effect of Prior Condition on Action for Malpractice.**—The Supreme Court of Vermont says, in the malpractice case of *Mullin vs. Flanders*, that the physician sued requested the judge to charge the jury that, if the diseased condition of the suing party's feet, or either of them, at the time and after the operation on them was performed, or her natural temperament or physical weakness, were contributing causes to the condition complained of, she could not recover damages. The judge declined to so charge, but charged that she could not recover for anything produced by those causes, or any of them; that the physician was liable, if at all, only for the injury to the party suing attributable to his fault. With reference to this, the Supreme Court says that the request, as a whole, was not sound, and that the physician had no reason to complain of the charge as given. Continuing, it says that the condition the patient is in when the physician is called affects the question of damages, but does not control the right of action. The right of action depends upon the continuing or intervening conditions that are due to a neglect of duty on the part

of the physician after the patient is in a condition that may result in permanent loss of health or limb, and the physician has been called upon and has undertaken to exercise his skill in arresting the progress of the disease, in caring for the wounds, or in setting the broken bones. When a physician takes charge of a case under such circumstances, he impliedly represents that he possesses, and the law places upon him the duty of possessing and exercising, that reasonable degree of learning and skill ordinarily possessed by physicians and surgeons in the locality where he practices, and which is ordinarily regarded as necessary to qualify him to engage in the business of practicing medicine and surgery. It is difficult, the court proceeds, to see how, under a holding such as the request called for, a physician could ever be chargeable for the neglect of a duty that the law imposes upon him. When a man is in good health, and sound in limb, he has no need of a physician. It is when disease takes hold of him, or when he has met with an accident, that the physician is called, and the duty attaches, and these conditions which exist at the time he takes charge of the case may be said to contribute to the permanent loss of health or limb which follows; but these conditions do not prevent a recovery for the damages that are due to his neglect of duty.

1. **Infant Diet.**—Winter's conclusions are: Chemistry, physiology, and chemical physiology, have furnished unerring guides for the feeding of children. The time when and what farinaceous substances should be given is wholly evident. Meat juice is contra-indicated in very young children, owing to its exciting effect on the nervous centers, and the loading of the system with extractives which tax the excretory organs. During all the years of early childhood, meat and its preparations should be given only sparingly on account of their over-stimulating metabolism, but chiefly for the reason that they create a distaste for cereals, fats, and fresh vegetables, thus depriving the system of materials needed to shield the proteins from oxidation that they may be stored for future needs, and of the necessary mineral salts which vegetables obtain direct from the soil. In a child, with its relatively large cutaneous surface and correspondingly rapid heat loss, the large demand for calories must not be covered by proteid to any considerable extent, otherwise there is a lack of deposition of proteid—or of muscle growth. Increasing quantities of carbohydrates and fats in the food decrease proteid metabolism; a more lasting deposition of proteids for future needs is thus brought about. To provide the mineral constituents necessary to maintain the normal reaction of the fluids of the body when these elements are being appropriated in large proportions for the growth of bone, muscle, etc., vegetables which obtain these elements direct from the soil must be consumed in fairly liberal proportions.

2. **Cutaneous Epithelioma.**—Allen reviews the theories of epithelioma and speaks particularly of the effects of x-ray

treatment, which he has seen in the practice of Pusey of Chicago and has employed to some extent himself. His experience has not yet lasted long enough to give him the authority to speak conclusively, but the results have been so far very encouraging. As regards the technique of the method he suggests caution and short applications in the beginning, protection of the parts not to be operated upon and a funnel-shaped metallic cone into the flare of which the active area of the tube is inserted, especially for mouth, throat, uterine and rectal work. After the first sitting it is well to wait a week before going on with the daily applications. The time of exposure may be gradually lengthened. If signs of dermatitis appear suspend the treatment until they subside. As regards the distance of the tube from the patient much depends on the length of exposure, the character of the tube, nature and size of the diseased area and the operator's experience. The most of his work has been done at rather close range, three to five inches. In specially severe affections as cancers, more chances might be taken as regards burns. We need not think that the cure would be delayed if the diseased parts do suffer from this cause. The time of exposure ranges between 3 and 30 minutes. He specially mentions the use of methylene blue, which he has painted over the diseased part coincidentally with the x-ray treatment. He prefers this to the use of blue media at a distance. If it does not shut out the burning rays it does not harm, but gives the patient the benefit of an added form of treatment not devoid of benefit.

**3. Tuberculosis Sanatoria.**—Pryor's report calls attention to the exaggeration of the contagiousness and communicability of tuberculosis and its bad effects. He thinks that we should now try to do something to counteract it. He calls attention to the cost in human life of tuberculosis and its field for study, and maintains that the time will come when this will be appreciated and public sanatoria be founded more generally. We must propagate the belief that pulmonary tuberculosis is curable during the early stage.

**6. Curettage of the Puerperal Uterus.**—According to Pryor the statistics found by the Commission of the American Gynecological Society in 1898 showed that the normal mortality of puerperal sepsis was 5 per cent., while those cases where curettage had been made and the streptococcus found gave the frightful mortality of 22 per cent. Since then he has adopted and practiced a method of treatment which he applies to all cases in which he found the streptococcus present and this has given him and others who have tried it no mortality excepting where curettage had been done before coming into his hands. In these there was 33 per cent. mortality. He considers that curettage of the septic puerperal uterus is a mischievous and exceedingly dangerous procedure.

**7. Cow's Milk and Infant Tuberculosis.**—Jacobi reviews the literature of intestinal infection from milk and holds that the infantile intestine is particularly disposed to absorption both in its normal and diseased condition, and that peritoneal tuberculosis is exceedingly frequent. Therefore, any rule prohibiting the sale and use of milk of cows with diseased udders or general clinical tuberculosis can not be strict enough or too strict. This is a very urgent hygienic and sanitary question.

**8. Tuberculosis Sanatorium.**—This paper calls attention to the need of sanatoria for the tuberculous poor and maintains that it would be a public economy and possibly in time lead to the control or extinction of the disease.

9.—See 179.

10.—See abstract in THE JOURNAL, xxxvii, p. 1555.

**11. Farm Colonies and Tent Life for the Tuberculous.**—The value of open-air treatment is emphasized by Freudenthal; he calls attention to economy in tuberculosis sanatoria by using tents instead of erecting elaborate hospital buildings. He also mentions the necessity of occupation. Tent life has been found beneficial even in winter by those who have experienced it and good results have been obtained by physicians treating consumptives in tents.

**14. Pancreatic Disease.**—The history of pancreatic disease, its leading symptoms, such as salivation, diarrhea, glyco-uria,

fatty stools, imperfect digestion of muscle fiber, pain, tumor, etc., are noticed, and also the etiology, chiefly infection. Murray reports three cases, one of suppurative pancreatitis, one of the gangrenous type and one of pancreatic cyst with remarks on each case report.

**15. X-Rays in Legal Medicine.**—Leonard's article is to some extent a criticism of a previous one by Golding-Bird on skiagraphs and their medicolegal relations. He believes that the x-ray may have the greatest possible value in the diagnosis, though the experience and skill of the operator must be relied upon, and skiagraphs used in evidence should be made with the greatest care. This method of diagnosis should not be feared, but courted for the scientific aid which it is capable of giving in the treatment of fractures. It is more accurate than any other and its employment should be demanded wherever feasible.

**17. X-Rays in So-called Sprains.**—The paper of Ross and Wilbert is devoted to the elucidation of actual conditions in many cases of so-called sprains. It shows by line illustrations a number of possibilities from actual cases in practice, fractures, dislocations, etc., where the diagnosis was simple sprain.

**18. Thiosinamin.**—The value of this drug, which is a white crystalline substance made from mustard oil by heating with alcohol and ammonia, is due to its causing increase in the leucocytes in the blood and its value in causing absorption of morbid tissues and scars. He reports six cases where it has been employed, including some of rheumatic origin with fibrous deposits. He questions the theory of uric acid set free by leucocytes and shows that the drug is not, as would be expected from it, a cause of acute attacks of rheumatic disorder. It may be said in general that it is, so far as we now know, useful in removing fibrous deposits due to disease and is not a germicide or an antirheumatic. The cases that he reports, he thinks, indicate that it will be found useful in aiding the absorption of rheumatic fibrous deposits.

**19. Bacillus Coli.**—The method used in the Laboratory of Hygiene of the Vermont State Board of Health is here described by Stone, the bacteriologist of the Board. As soon as the water is received steps are taken to obtain: 1. An estimate of the total number of bacteria per cubic centimeter. 2. The determination of the presence or absence of bacillus coli communis. 3. If this organism is present the estimation of the number of bacteria per cubic centimeter. The estimation of the total number is made by thoroughly shaking up the water before diluting 1 c.c. with 99 c.c. of distilled water previously measured and sterilized. A 1 c.c. of the diluted specimen is then taken by a sterilized pipette and mixed with a tube of plating agar melted at a temperature of 40 C.

This agar, containing 0.01 c.c. of the original water, is then turned into a sterilized four-inch Petri dish and allowed to solidify on a level table. The plate is placed in a room temperature incubator (22 C.) and grown for 96 hours when it is removed and the number of colonies on the plate are counted. This number multiplied by 100 represents approximately the number of individuals per c.c. of the original water.

**Determination of the Presence of Bacillus Coli Communis.**—A. A Smith's tube filled with a 2 per cent. glucose bouillon is inoculated with 1 c.c. of the water to be examined and grown 24 hours at 38 C. If no gas is formed, the absence of the colon bacillus is shown.

B. If from 25 to 70 per cent. of gas is formed in the closed arm, a tube containing 10 c.c. of neutral broth to which has been added 0.3 c.c. Parietti's solution is inoculated with 0.5 c.c. of the contents of A. and grown 24 hours at 38 C.

C. A second Smith's tube is inoculated with 0.5 c.c. of the contents of B. and grown 24 hours at 33 C. (If there is no gas, we may be sure the gas producer in A. was not the colon bacillus. If, on the other hand, gas is produced in this tube, we may be reasonably sure that the bacillus coli communis is present.)

D. Further confirmation may be obtained by ascertaining the gas formula from C. The formula for the colon group is  $H_2/CO_2-2/1$ , further.

E. A pure culture can be easily obtained from B. by plating and the following reactions obtained: (1) Gelatin stab does not liquefy after seven days at 22 C. (2) Litmus milk reddens and coagulates in 24 hours at 37 C. (3) Dunham's solution: Indol formed in three days at 37 C. (4) Morphology in bouillon: sluggishly motile (?) bacillus.

**Estimation of Numbers of Bacillus Coli Communis.**—At the same time the plates for total numbers are made, a litmus lactose agar plate of 0.5 c.c. of the original water is made. After solidifying, this plate is inverted and grown 24 hours at 38 C. when the colonies of bacillus coli communis may be identified as red colonies on a blue plate.

The following organisms have been subjected to this method, but only bacillus coli communis and the allied bacillus of hog cholera survive the check solution *B.* and grow in the second fermentation tube: *Bacillus pyocyaneus*; *bacillus prodigiosus*; *bacillus cloacae*; *bacillus liquefaciens*; *bacillus aerogenes capsulatus*; *bacillus of lactis acid*; *bacillus lactis aerogenes*; *bacillus coli communis*; *bacillus of hog cholera*. *Bacillus coli communis* from many sources has been tried and in all cases survived the process.

Up to date we have had 550 specimens of water put through this process and we have yet to find an organism surviving the check solution and growing with gas production in the second fermentation tube, which does not give every typical growth reaction characteristic of *bacillus coli communis*.

**21. Idiopathic Dilatation of the Esophagus.**—Strauss reports a case which is of note on account of the very large amount of dilatation and discusses the condition. His view of the causation of the dilatation is that a developmental obstruction causes stenosis of the lowest portion of the esophagus, the "pars sphincterica inferior" as he calls the region between the hiatus and the cardia, and that a secondary dilatation is brought about by irritation of the mucosa by stagnation, causing inflammatory or excoriation conditions, and these producing spasms in the cardia which become the cause secondarily of progressive dilatation of the esophageal wall. He thinks that we must, however, look for the most certain cause of vascular dilatation of the esophagus without anatomically demonstrable stenosis, to be the coincidence of several synchronously acting factors.

**22. Gastropptosis.**—From a study of a large number of cases Steele finds that ptosis is more common in motor insufficiency of the stomach than changes in the shape and size. Gastropptosis and pyloric dilatation occur in 43 per cent.; next in frequency, was general dilatation alone, 35 per cent.; and then comes gastropptosis alone, 20 per cent., while the least common of all is general dilatation and gastropptosis, 10 per cent. Gastropptosis is much more common in females, while in males general dilatation is more common, uncomplicated dilatation especially. These figures show that ptosis of the stomach is more frequent than has been supposed. In women showing demonstrable alteration in the position and size of the stomach its presence is almost constant. The condition divides itself into two varieties; 1, total displacements downward; 2, that of the pyloric end alone. The latter is much the most common. The former has been denied, but that it exists is shown by the cases reported and simple ptosis of the stomach may be associated with more or less dilatation. The probability is that in pyloric dilatation the primary condition is gastropptosis, while in general dilatation in a large percentage the dilatation is primary. The causes are discussed. A very frequent one is increase in the volume of the abdominal cavity; another is pressure from above. The conditions most often associated with increase in the abdominal volume are repeated pregnancy and too early assuming the erect posture after parturition, while the most frequent cause of downward displacement is pressure from above, the effect of tight lacing or dragging of the skirt band. Glenard's theory that all displacements of the abdominal viscera arise from the presence of adhesions is now generally rejected. J. C. Webster has called attention to the separation of the recti muscles in some cases where the associated enteroptosis is really a form of hernia. Steele advocates a routine examination of the size and position of the stomach as indispensable in all cases showing functional disturbance. The patients are usually emaciated and often anemic, the abdomen sometimes pendulous, sometimes flat, but characteristically relaxed. The "belt sign" of Glenard may be employed, which consists in standing behind the patient, placing the hands on the lower abdomen and lifting upward and backward. If a sensation of relief is felt it is assumed that downward displacement is present. Webster demonstrates the amount of separation of the recti muscles by placing the finger tips of the right hand over the linea alba near the umbilicus with the patient in the recumbent position, while with the left he grasps the patient's hand, and she is asked to raise the head and chest in order to contract the abdominal muscles. The sense of resistance afforded by the recti will give an idea of the extent of their separation. The other diagnostic methods are discussed. Inflation, palpation, auscultation, etc., are

noticed at length, also Einhorn's gastric illumination. The most common of the direct results of downward displacement are motor insufficiency and dilatation. Changes in the gastric secretion occur. Subacidity or the absence of free HCl seem to be the most numerous according to Steele's observation, and of importance as indicating the dietetic treatment. The complications of neurasthenia and sclerosis are mentioned. They are absolutely inter-dependent with the gastric abnormality. The treatment should be by the relief of the causes—tight lacing and the hanging of heavy clothing from the waist band. Food should not be given in too large amount at a time and rest should be allowed after eating. The stomach should be held in place by an abdominal band, which should be held against the tubes by perineal bands and one or more pads adapted to exert upward pressure will be found most useful. The operative measures that have been recommended are noticed, but the author holds that it is impossible to say whether or not they will give permanent relief. Still the recent experience of Bier, Blecher and Webster are encouraging.

**24. Vaccination.**—The various skin eruptions associated with vaccination are described by Van Harlingen, who groups them under the pure vaccinia and the mixed inoculation types. In the former he includes the secondary inoculations which may occur, and various angioneurotic conditions following the irritation. The generalized vaccinia is somewhat different in its character from the other eruptions and somewhat analogous to a general outbreak of infectious disease following a period of incubation. The impetigo or eczema attributed to the operation are really due to mixed inoculation. Syphilis, leprosy, etc., have been reported in the old days of humanized vaccine, but he doubts whether there is any case of true tuberculous infection thus produced. He insists on attention to cleanliness in vaccination, though asepsis might be carried so far as to make the virus itself inert. Shields are useful only for the first few days; if retained longer they may do harm as becoming themselves cultivation houses for pathogenic germs. After the first few days, or as soon as the vaccine virus has invaded the system, which is shown by the red and infiltrated areola, the shield should be cast aside, and antiseptic dressings frequently changed should be adopted.

**26. Multiple Neuritis.**—Starr reviews the various causes of multiple neuritis, the toxic metallic poisons such as arsenic, lead, mercury, copper, phosphorus and silver; and non-metallic toxic poisons such as alcohol, carbonic oxid, bisulphid of carbon, sulphonal and trional, the coal-tar products and nitrobenzol, all of which are noticed at length. Alcohol seems to be the most frequent of all the causes. The second type is that of multiple neuritis from dyscrasia. In this class he gives the epidemic form known as beri-beri and leprosy neuritis, and that occurring as an accompaniment or sequela to diphtheria, which he holds is less frequent since the use of antitoxin. He emphasizes the frequency of neuritis following la grippe from which cause he has noticed all types. There are certain other dyscrasias such as tuberculosis, rheumatism, gout and diabetes; there are also cases of general multiple neuritis, occurring in the carcinomatous and in old persons with atheroma. It is probable that syphilis does not enter as a factor in the etiology of this affection. Finally, he alludes to certain cases where the cause can not be determined which we must call idiopathic and reports such a one. A double causation may many times be ascertained. Thus arsenic and lead poisons may act together with alcohol or la grippe.

**32. Appendicitis.**—Lymphatic and portal infections, singly or combined, are not as infrequent after appendicitis as many would hold. The obscurity of the symptoms and the insidiousness of their approach obscure the cases. Practically all lymphatic infections are curable by operation. Only a rare case of hepatic infection will be cured, but if the cases are allowed to go on until they become septic skeletons, the chances are almost hopeless. He says, in brief, that a persistent temperature, during or following appendicitis, inconsistent with other lesions and associated with lumbar spasm should suggest a lymphangitis; more or less perhaps fleeting jaundice, irregu-

lar chills, hepatic tenderness and progressive emaciation should suggest portal pyophlebitis following appendicitis, present or remote. He gives cases showing the occurrence of these complications.

**33. Anesthesia.**—Mosher recommends the use of a treadle arrangement for forcing ether vapor through a tube by means of bellows, which has been brought up to its present form by Drs. Thomas Fillebrown and M. F. Rogers, as specially advantageous in operations on the nose and throat. He favors ether rather than chloroform and gives details as to holding the patient, preferring to keep him in the upright position. The prejudice against this is groundless. Experiments on animals are mentioned that seem to show that stimulation of the pharyngeal plexus might cause stagnation of the heart by reflex action, but he thinks in the human species this hardly possible, but it might nevertheless be well to give atropin as a routine preventive measure.

**34. Radio-Active Substances in Therapeutics.**—Rollins suggests the use of a radio-active substance as a substitute for *x*-light. He has prepared a capsule containing 500 mgm. of radium with an aluminum front and back comparatively non-radiable metal, which is to be worn over a lupus or superficial cancer or whatever disease it is desired to treat with these rays. He does not give any experience with it, but offers this suggestion.

45.—This article has appeared elsewhere. See THE JOURNAL, xxxvii, §23, p. 1561.

47.—Ibid., §84, p. 279.

50.—Ibid., 277.

**57. Spinal Fracture.**—After discussing the symptoms and reporting several cases Walton gives the following conclusions: "1. There are no symptoms which establish (otherwise than through their persistence) irremediable crush of the cord. 2. While total relaxed paralysis, anesthesia of abrupt demarcation, total loss of reflexes, retention, priapism and tympanites, if persistent, point to complete and incurable transverse lesion, the onset of such symptoms does not preclude a certain degree at least of restoration of function. 3. The prognosis without operation is grave. 4. While the results of operation are not brilliant, they are sufficiently encouraging to warrant us in making the practice more general. 5. In most cases it will be wise to operate within a few days of the injury, but a delay of some hours is advisable, partly on account of shock and partly to eliminate the diagnosis of simple distortion. 6. We have no infallible guide to the extent of the lesion. The operation at the worst does not materially endanger life nor affect unfavorably the course of the case, and may at least reveal the lesion and lessen the pain; it may sometimes save a patient from death or from hopeless invalidism of most distressing character. Instead of selecting the occasional case for operation, we should rather select the occasional case in which it is contra-indicated (the patient with great displacement of vertebrae, the patient with high and rising temperature, the patient plainly moribund, the patient still under profound shock). 7. The dura should be opened freely; it need not be sutured; drainage is not necessary."

64.—This article has appeared elsewhere. See THE JOURNAL, xxxvii, p. 863.

**67. The Microscope in Otorrhea.**—Saydacker reports three cases illustrating the value of the microscope in the detection of cholesteatomata and traces of carious bone. In each of these the findings warranted a radical operation, but in all three the patients refused to submit to it. He remarks that the presence of shreds of epidermis may not always indicate cholesteatomata, but simply a sort of reparative process. Only when the discharge persists after the epidermal formation has begun, when by its constant irritating contact it causes over-production of epidermis and this is constantly cast off, it may be regarded as a dangerous symptom. Only the discharge persisting for weeks and months should be considered dangerous. The appearance of bone disease may possibly not be a serious indication if it comes only from the ossicles, and the tympanic

walls and mastoid cells are intact. The observations, however, of Grunert, who finds only two cases where the ossicles alone were involved out of a total of 108, indicate rather that the presence of carious bone has a bad signification.

70. See THE JOURNAL, xxxvii, p. 1721.

**79. Paratyphus.**—Meltzer discusses the cases of apparent typhoid which do not react to the Widal test. He says we have a description of a disease which already has been observed more than a dozen times and which clinically must be considered as typhoid, but in which repeated examination with the Widal reaction is negative. On the other hand, the sera of these patients react readily to bacilli which are isolated from the blood or from excrement. These bacilli belong to the intermediate group closely related to the meat-poisoning bacilli, but are decidedly distinct from these. The symptoms of the patients are, as already stated, exactly as in typhoid: headache, depression, continued fever, slow pulse, enlargement of the spleen, roseola and the diazo-reaction; also nose-bleed and intestinal hemorrhage, delirium, slight affections of the respiratory passages, post-typhoid osteomyelitic abscesses have been observed. All the patients recovered; there is yet no pathologic anatomy of the condition. According to Kurth's view these cases are of milder course than in true typhus and he thinks the old designation of gastric fever might be employed, but that of Schottmüeller and one described by Gwynn certainly were severe. In seven of the cases the condition commenced with diarrhea which passed later into constipation, a condition which one rarely sees in typhoid. Gwynn has called these germs paracolon bacilli. Kurth and others have given various names, but the author prefers Schottmüeller's designation of paratyphus bacillus. He thinks that in many cases there may be a mixed infection of typhoid and paratyphus and the Widal reaction occur late. See also §9 above.

**85. The Cystoscope.**—The history of the cystoscope is given by Foote, who prefers the Berlin pattern of instrument. He considers cystoscopy usually an easy and safe method of diagnosis of gastro-intestinal disease, which should be made in every obscure case and by it the presence of disease in one or both kidneys can be determined in almost every instance. Hence, its value as a preliminary to operation on the kidneys, since it renders the differential diagnosis between vesical and renal disease comparatively easy.

**87. Jamaica as a Health Resort.**—The advantages of Jamaica are described by Adams, who gives the cost of living there in detail, showing that quite a variety of diet can be had at comparatively moderate prices. He also mentions the mineral springs and baths. The climate, according to him, seems to be a very desirable one for a large class of invalids.

**88. Syphilis of the Rectum.**—The most common syphilitic manifestations in the rectal region are condylomas, which are often called piles, but, if uncomplicated by ulceration, usually rapidly disappear when treated by internal medication and the local use of calomel as a dusting powder, with daily ablutions with a weak solution of mercuric chlorid. Chancres are comparatively rare. Ulceration may occur during the secondary stage, but most frequently during the tertiary, and is due to gummatous deposits and infiltration of the submucous tissue. Gummata have been known to obstruct the bowels, but they usually disappear rapidly under the aggressive use of iodid. Infiltration may produce a fibrous condition with great contraction, and stricture is sure to follow syphilitic ulcer. If this occurs in the secondary stage the use of mercury is indicated. For the third the iodid or mixed treatment is best, but it must be remembered that at times the third stage seems to anticipate itself and a mixed treatment early required. It is well not to continue the internal administration of mercury when we suspect ulcerative papillitis of the rectal mucosa. We should use injections so as to rapidly produce the desired effect and at the same time keep the bowel clean with semi-daily enemas of creolin solution. Codein may be given for the pain or tenesmus. Hawkins finds it advisable to use sulphocarbolate of zinc 20 gr. to quart of warm water in an enema once or twice daily. In some cases divulsion of the sphincter

is necessary to secure proper drainage and the relief of pain. When syphilitic stricture exists it is advisable, he thinks, to use posterior linear proctotomy with the subsequent use of bougies, but he would give a very guarded prognosis, especially as regards the cessation of discharge. Ulceration is apt to persist and iodine does little good. Colostomy is all that remains for many of the cases, and it should be recommended as no worse than the disease. It allows the diseased surface to be kept clean and free from irritation.

**89. The Climate of California.**—The Colorado physicians, according to Bonney, are ready to admit that California is specially beneficial for certain cases of tuberculosis. He has been sending there many cases with bronchial disorders, cases of emphysema and certain forms of heart, kidney and rheumatic troubles, and has had satisfactory results. He does not endorse the prevailing opinion that nervous patients are aggravated in Colorado. He thinks possibly cases with hemorrhage err in making the trip to high altitudes too rapidly. A reasonable delay before starting and a period of rest immediately on arrival will obviate the unfortunate results. The hemorrhages that occur in Colorado are largely due to such cases and they occur most frequently in the spring, which he attributes to the winds and dust. During the spring he has been sending patients up to an altitude of 7500 feet and has never had a hemorrhage occur at Estes Park during the past six years.

**90. Fractures of the Femur.**—Babeock describes a rectangular splint suspended from a support which keeps the muscles of the thigh in relaxation. He has used, to his entire satisfaction, an ordinary anterior-angular arm-splint. The longer arm should have a length equal to that from the popliteal space to the heel; the shorter arm, a length equal to that from the popliteal space to the great trochanter. It should be slightly broader than the thigh and well padded. In applying it the leg is flexed to a right angle to the thigh and the thigh to a right angle to the body, and displacement corrected and the splint snugly fixed to the posterior aspect of the limb by several strips of adhesive plaster. The leg is supported in extension while the splint is carefully bandaged in position. The apparatus is swung from a point of support above the bed, the chief support attached at the angle of the splint and the extension sufficient to raise the corresponding hip slightly from the bed. The weight of the foot is carried by a bandage passing under the splint at the ankle; this is for support, not for extension. The position is not an uncomfortable one, while the center of gravitation is carried so far into the upper part of the body that active movement of the trunk or legs is discouraged. It has been a surprise to see how quietly children have stood the application of the apparatus.

**93. Fistula in Ano.**—The differential diagnosis of fistula in ano in its simple type from its tuberculous form, is described by Gant. Tuberculous fistulae are usually secondary to intestinal ulcer caused by tuberculosis of some other organs, as the lung. Non-tuberculous fistulae frequently occur in phthisical subjects also, due to emaciation, proneness to suppuration from slight causes and the result of bruises of the parts. The chief diagnostic points are the appearance of the rounded and elevated openings of the non-tuberculous forms, rounded buttocks, normal hair, nails, face, ears, and nose and voice; discharge is slight and yellow instead of profuse and watery or whitish; greater pain is caused by the introduction of the probe; lack of complications of cough or hemoptysis, tight sphincter as compared with patulous anus in the tuberculous, and the absence of tubercle bacilli.

**99. Insects and Disease.**—McFarland sums up the possibilities of dissemination of disease by insects in the following methods: 1. They may carry from place to place disease-producing micro-organisms on their bodies causing infection directly by lighting upon wounds and indirectly by alighting upon foodstuffs. 2. They may carry within their body germs of disease which have entered them by food and may subsequently be deposited elsewhere with the feces. This has been demonstrated in connection with tuberculosis. 3. The suctorial insect, by taking blood containing parasites from the

bodies of diseased animals, may carry these upon their proboscides into the next animal bitten, directly and immediately affecting it. There are many cases in which anthrax has been apparently brought about in this way. Plague has been said to be thus disseminated, and tsetse fly disease is quoted as being thus produced. 4. Insects may take infectious germs into their bodies and transmit them to their offsprings, whose bites are infectious, as in cases of Texas fever of cattle. 5. Insects may take into their bodies parasitic organisms which there undergo a further development, the insect acting either as an intermediate or a definitive host, and transmitting the parasites to other animals in some changed form in which they are infective. The malarial organism is quoted at length as belonging probably to this class. Yellow fever is probably still another, also filariasis, all three disseminated by the different species of mosquito. 6. Insects may become infected with pathologic organisms and by falling into foodstuff thus impart infection to man. Such accidents are probably rare, but still it has been found that a fly can become infected with plague and die of the disease. The danger that might lurk in such an insect cadaver need not be dilated upon.

**101. Alcohol.**—Heredity of alcoholism is divided by French into three classes: 1. It may be direct, where there is a susceptibility and craving for it transmitted from one generation to another, the form remaining substantially the same. This is not uniform among children and it may skip a generation. Persons with such heredity can not be moderate drinkers, and can only escape inebriety by avoiding alcohol entirely. 2. It may be indirect as where inebriety in the parent or some remote ancestor has resulted in degenerated conditions and degeneracy which may suddenly break out into inebriety in some later generation. 3. The heredity may be complex as where various forms of degeneracy, disease and mental and nervous affections exist in several generations and finally result in inebriety in the succeeding one. He also mentions mental and moral heredity and quotes Morel and others. He concludes that alcohol is the greatest cause of degeneracy; both mental and physical; when not an inebriate, the hereditary victim is likely to be diseased, degenerate, mentally unstable or unbalanced, fanatical, eccentric or a genius. The hereditary inebriety develops rapidly at the first exciting cause and subjects of it can not indulge in alcohol safely. Alcoholism in such is difficult to cure and when apparently cured relapses are very liable to occur.

**102. The Pancreas in Diabetes.**—Herzog reviews the papers on the subject of the condition of the islands of Langerhans in diabetes and reports microscopic examinations of three cases. The results of examination are well in accord with what has been recorded by Scobolew, Opie, Weichselbaum and Stengel. The degeneration of the islands of Langerhans or changes in their structure are largely of the character of fibrosis.

**113. Appendicitis.**—Ochsner reiterates his views in regard to the treatment of appendicitis by gastric irrigation and nourishment only per rectum. His mortality since he has employed this method is less than one-fourth as high as it was in cases operated upon at once on making the diagnosis. Even in advanced cases of diffuse peritonitis there has been a marked decrease in the mortality. In many cases he has removed the appendices later and shown that the condition was not simply a severe catarrhal one. As a result of his clinical observation he formulates the following conclusions: "1. Peristaltic motion of the small intestines is the chief means of carrying the infection from the perforated or gangrenous appendix to the other portions of the peritoneum, changing a circumscribed into a general peritonitis. 2. This can be prevented by prohibiting the use of every kind of food and cathartics by the mouth, and by employing gastric lavage in every case in which there are remnants of food in the stomach or in the intestines above the ileo-cecal valve, as indicated by the presence of nausea or vomiting of meteorism. 3. The patient can be supported by the use of concentrated predigested food administered as enemata not oftener than once in four hours, and not in larger quantities than four ounces at a time. 4. This form of treatment, when instituted early, will change the most

violent and dangerous form of acute perforative or gangrenous appendicitis into a comparatively mild and harmless form. 5. Cases of perforative or gangrenous appendicitis with beginning general peritonitis can usually be carried through the acute attack safely with this method. 6. In all cases of this class gastric lavage should be practiced in order to prevent the absorption of decomposing material from the alimentary canal. 7. In cases of doubtful diagnosis this form of treatment should always be employed. 8. This treatment will prevent a large proportion of the most troublesome complications and sequelae of appendicitis, such as ventral hernia, fecal fistula, extensive adhesions, etc. 9. The patient should be permitted to recover fully from his acute attack before an operation is performed, except in cases encountered within the first thirty-six hours after the beginning of an attack or in case of the formation of a superficial circumscribed abscess. 10. It often requires but a small amount of any kind of food to change a harmless circumscribed into a dangerous diffuse peritonitis. 11. The treatment does not protect the patient against a subsequent attack. 12. It does not contra-indicate the removal of a diseased appendix before the septic material has extended beyond this organ. 13. It is indicated in all intra-abdominal conditions in which it is desirable to prevent the distribution of septic material by means of peristaltic motion. 14. The laity should be taught to stop feeding and giving cathartics to patients suffering from intra-abdominal diseases."

129. **Fistula.**—Tuttle reviews the whole subject of fistula, calling attention to the importance of thorough study of physical, clinical and pathologic characteristics and making complete diagnosis in every case. He maintains that the percentage of failures in fistulous operations exceeds that of operations for cancer of the rectum. He thinks this statement may hardly be believed. Eternal vigilance is the price of healing in any of these cases. The surgeon can not safely dismiss the patient until every vestige of granulation and soft inflammatory tissue has disappeared. The causes of failure in many of these cases are imperfect drainage and persistent infection; he insists on thorough disinfection of the wound. In tubercular fistula, healing does not take place because of the pathogenic bacilli in the wound. In non-specific fistulas, complete drainage or radical removal of the entire fistula by incision with immediate suture is essential. It is not necessary always to cut through the fistula at once; cauterization will often give better results if it is done thoroughly. To be effective nitrate of silver should be used in solution in the strength of 900 to 1000 grains to the ounce of water and be applied thoroughly to the fistulous tract. He suggests one or two points in regard to the technique of the incisions, especially in deeper fistulas where this blind cutting from within outward is not only dangerous but unsatisfactory. The fistulous tract may be accurately followed and laid open on the skin until it reaches a point directly below the internal opening and then the internal tissues and muscles are cut squarely across. It is not necessary to incise the intestinal wall as high up as the perirectal abscess burrows. Excision of fistula with immediate suture is being more and more employed. He gives two or three little practical points: 1. Not to chromicize catgut to last more than six or seven days as too much chromicization makes it a permanent and irritating body. The deep wound should be brought together with a continuous mattress suture so as to avoid knots as far as possible, but this same suture should not be used to bring the edges of the external wound together. The ends of the muscles should be brought together by interrupted sutures of the mattress type, and composed of chromicized catgut, for at this point we need a prolonged maintenance of the part in position. After the deep wound has been brought together the skin should be united by interrupted or continuous silkworm-gut suture. The incision into the rectum should be treated as follows: The mucous membrane should be dissected off from each side of the wound to the extent of one-half an inch up to the level of the internal opening of the fistula. From this point upward it should be loosened sufficiently from the muscular wall of the gut to be brought down and attached to the skin just below the margin of the anus, after the manner

of a Whitehead operation. This seals off from the intestinal canal the field of operation by healthy tissue and helps in obtaining union by first intention. In tubercular fistula only two courses are open: If the fistula is direct and can be thoroughly excised in all its extent and the wound immediately sutured, this should be done, but it should be as thoroughly done as in cancer operation. If the tract is wide and tortuous, making removal of all the pathologic tissue impossible, it should be thoroughly drained by a dependent incision upon the outside and the fistulous tract treated by methylene-blue, orthoform, or the Roentgen rays. Incision for drainage should be made with a Paquelin or electro-cautery so as to prevent the entrance of the bacilli through the wound. In tuberculous patients any surgical intervention is of doubtful benefit except where the opening is too small for proper drainage. Syphilitic, typhoid and dysenteric fistulas should be treated as in the simple non-specific type, at the same time employing what constitutional treatment is required.

130. **Circumcision.**—Spitzley argues for circumcision as a preventive of venereal disease.

135.—See editorial in *THE JOURNAL* of January 25, p. 253.

144. **Iodic Purpura.**—Stengel first briefly reviews the literature, the character of the eruption, the associated symptoms, joint manifestations and fever and the amount of iodism required. He shows from Robinson's case that a very minimum dose may produce this, even 1 gr. three times a day. In most cases, however, 3 to 10 gr. repeated three or four times a day were required, and he reports and illustrates cases of this condition and calls attention to certain symptoms suggesting Graves' disease, such as tremor, thyroid enlargement, cardiac palpitation, skin relaxation and sweating. These facts are rather suggestive of an actual state of the chronic iodism in Graves' disease itself. The diagnosis is ordinarily not difficult, but in the instances like the one reported there was some suspicion of constitutional or possibly cardiac disease; the suggestion of ulcerative endocarditis embarrasses the diagnosis.

146. **Tuberculosis.**—The value of tuberculin in the treatment of tuberculosis is pointed out by Pottenger, who from a careful review of the subject comes to the following conclusions: "1. Culture products do have a specific action upon tuberculous foci. 2. That this has not been recognized is due to the early unfortunate experience with tuberculin: (a) When it was used in too large and too frequent doses; (b) when it was employed in unsuitable cases; (c) when it was held responsible for all postmortem findings. 3. The field of usefulness for culture products is where recent tubercles are found, and this especially in incipient cases. 4. If used in advanced cases, culture products will help remove areas of recent extensions, but must not be expected to remove dead, decaying or newly formed tissue. 5. When culture products are used, they should be reinforced by every means at command. Every phase of the patient's health should be cared for, and the proper hygienic and dietetic measures prescribed. 6. When the case is managed properly and culture products are used, the proportion of cures is greater than when culture products are not used. 7. Culture products produce an immunity which protects the patient from relapses; hence, make a permanent cure more often than hygienic and climatic treatment alone, which fact of itself should be enough to warrant their use in all suitable cases."

155. **Glandular Fever.**—West describes two cases and discusses glandular fever, what he considers as a distinct disease. He thinks there are no grounds upon which to suppose it to be a modified type of any other known acute infection nor any irregular form of any of the acute exanthematous diseases. The symptom-complex resembles catarrhal influenza in its sudden onset, high temperature, muscular soreness, prostration and slow convalescence. There is also enlargement of groups of nodes in influenza, but this is due to and commensurate with local lesions, and suppuration is not uncommon. In glandular fever this local inflammation does not exist or is so slight as to be wholly unaccountable for the trouble. The catarrhal symptoms are also fully as prominent in influenza as the gen-

eral ones. Almost all theories point to this disorder as an infection from the intestinal canal, and facts, he thinks, also point to this. The milder cases are accompanied by diarrhea, the severer by constipation and in every case relief only follows the remedying of the condition. Influenza is an epidemic disease, while glandular fever is restricted to house epidemics and rarely affects adults, and Pfeiffer's bacillus has not been found.

156. **Blackwater Fever.**—Blair describes the health conditions as he has observed them on the west coast of Africa. He gives a very unfavorable description of the malaria of this region and of the prospects of its abolition. He adopts the view of Stephens that blackwater fever is essentially a malarial disease in which quinin is the most common immediate determining cause of intoxication and that protection from malaria will protect from blackwater fever.

158. **Measles.**—Newcomb advocates the examination for Koplik's spots as a constant early sign of measles. He believes that segregation should be resorted to in each individual case, separating patient from patient, especially in hospitals. The dangers of overcrowding have been shown time and time again in epidemics.

1. **Obstructive Jaundice.**—In the diagnosis of obstructive jaundice Mayo Robson considers the following causes must be taken into consideration: 1. Common duct cholelithiasis. 2. Chronic pancreatitis. 3. Simple stricture of the common duct. 4. Inflammatory adhesions causing pressure on or stenosis of the hepatic or common ducts. 5. Hydatid disease pressing on or discharging into the bile duct. 6. Gummata implicating the ducts. 7. Chronic catarrh. 8, 9, 10. Cancer of the common bile duct, pancreas or liver. 11. Cirrhosis of

the liver. 12. Other rare causes such as aneurysm of the hepatic artery or aorta, and other tumors of the liver, gall-bladder, pylorus, kidney, etc. In the first five causes surgery affords good prospects of cure. Medical treatment is advisable only for gunnata or chronic catarrh of the bile duct, while malignant disease is not hopeful and all the remaining cases should depend according to circumstances on medical or surgical treatment. If the diagnosis is doubtful he thinks exploratory operation is advisable provided the general condition of the patient permits it. In malignant disease there are certainly two cases where operation can do no good. They are primary cancer of the liver and cancer of the head of the pancreas. However, in younger patients the operation should be seriously considered. In cases of suspected pancreatic cancer, which usually occurs later in life, chronic pancreatitis may only exist and be curable by drainage of the gall-bladder. As regards gallstones the two greatest causes of mortality are hemorrhage and shock and the next most serious, exhaustion and sepsis. Accidents such as heart disease, syncope, etc., may occur after any other operation. In his own experience of some 200 cases he finds a decided reduction of the mortality, especially in choledochotomies, where it has fallen nearly one-half. This he thinks is largely due, 1. to increased experience, accuracy and diagnosis and in the better selection of cases; 2. knowing when to stop after exploration; 3. by improving the technique of the operation by the preliminary and subsequent treatment; 4. increased practice enabling the operations to be accomplished in little over half the time they once required. In the free use of calcium chlorid the coagulating power of the blood can be modified, but it should be given at least two days before operation and longer with nutrient enemata for three or four days afterwards. Adhesions should be ligatured where possible and all the bleeding points in the parietes and inside the abdomen be clamped and ligatured, or if general oozing exists pressure by means of sterile gauze should be employed. For preventing shock the enveloping of the patient in cotton-wool, operating on a heated table, administering strychnin before beginning the operation, large normal saline enemata with or without drainage one-half hour before operating and immediately after, are the essential modes of treatment; the most important point perhaps is the cultivation of the habit of operating expeditiously, every minute's prolongation of the manipulation and of the anesthetic adds to the risk. Even the most complicated cases of choledochotomy should not occupy much longer than an hour and simple exploratory operation only ten or fifteen minutes. Exhaustion and heart failure are best met with rectal alimentation, judicious mouth-feeding as soon as the anesthetic sickness has ceased and the use of small doses of strychnin hypodermically is often called for. Regular all-around asepsis and the employment of gauze drainage where necessary and the careful removal of the infected bile to insure against sepsis are essential.

**3. Ophthalmic Work in the Army.**—After reviewing his experience with recruits, Grimshaw offers the following suggestions: "1. Do not admit more ametropes by still further lowering visual tests unless prepared to correct their vision. 2. The examination of such ametropes by ophthalmic experts (civilian or military) and their vision and correction to be recorded on their medical history sheets. Such action would be necessary not only to treat the 'scrimshanking and discharge' stages of a soldier's *folie circulaire*, but to render easy the replacement of broken or lost glasses. 3. Opticians to be officially appointed whose duty it would be to keep an exact record of glasses supplied, to check the regimental data. 4. The distribution of recruits according to their sight to branches of service not necessitating keen vision or otherwise. If the visual tests were lowered, it would be of paramount importance to separate the 'hewers of wood and drawers of water' from the soldier who proposes to become a good rifleman, cavalry man, or artilleryman. 5. To support discipline, and to lessen the responsibility of medical officers by inflicting summary punishment—by courtmartial and under the certificate of the ophthalmic surgeon—on soldiers afflicted with *folie circulaire* of above type. 6. To encourage the correction of ametropia by

granting spectacles to soldiers free of cost. I never could understand why free spectacles were given to South African invalids conditional on their discharge from the army. I should have thought that a non-discharge was a more rational condition. The War Office grants artificial teeth to men who are likely to become efficient soldiers and who are willing to remain in the army. Why not spectacles? 7. Official encouragement to R. A. Medical Corps officers to specially qualify themselves in ophthalmic work, such special qualification to be rewarded with corresponding increase of pay. 8. The appointment of civilian consultants in certain military centers or districts to coöperate with the R. A. M. C. officers as occasion demanded or rendered desirable. 9. Special arrangement to be made whereby spectacles lost or broken can be replaced, and for ensuring suitable glasses being always available on occasions of need. This applies specially to men abroad or on active service."

**4. Ruptured Tendo Achillis.**—Thomas gives his experience in the treatment of this condition on himself from an accident which occurred on shipboard. The splint applied by him was an aluminum spatula molded to the shape of the bend of the ankle, pushed into a very thick india-rubber tubing, which acted not only as padding, but also kept the splint in place by preventing the aluminum from moving downward under the bootlace. This was inserted under the lacing of the shoe and held in place by it. One of the essentials is that the shoe lace should be placed right around the lower part of the splint, because he finds that if the whole of it was in front of the splint the pressure on the back of the foot became intolerable. Massage was also kept up. The advantages of such a splint are its simplicity and efficiency; the patient can walk without any fear of getting the ankle flexed to a degree which would disturb the provisional callus. It answered the purpose in his case, enabling him to get around and leading to complete recovery. He thinks the treatment by early massage and walking in cases of ruptured Achilles tendon brings about a stronger union than is obtained by immediately suturing or the fixation of the limb by splints, because the call to provide sufficient reparative callus to bind the ruptured ends of the tendons is much greater during movement in the dependent position than it is during rest in an elevated or flexed position. He calls attention to the importance of the H-shaped bruise at the heel as a sign of rupture or division of the tendon.

**5. Cancer.**—Mason gives a series of statistics and observations which lead him to believe that cancer is due to some germ whose habitat is in the sewage contaminated subsoil and that its entrance into the organism is through one of the mucous-membrane lined apertures of the body. This will account for the following facts: "1. That the cancer death rate has increased during the last sixty years—a time synchronous with the development and extension of the water closet system of drainage, bearing in mind that the first style of water closet system was simply unglazed drain-pipes, laid end to end, sometimes joined with clay and sometimes without. I have even seen in old cancer houses drains made up of one brick laid flat, with two placed edgewise, and covered with slate running beneath the dwelling house. 2. That the infection of the alimentary system is as high as 55 per cent. For in those houses in which the drains are in such a faulty condition as to contaminate the subsoil, the food, which is often kept in the cellars, would be the first to become infected by any germ that might be existing in the subsoil, considering there is always an upward current of air out of the subsoil into any building upon which it is built. 3. That people over 40 years of age are more subject to it, as they become more confined to their dwelling as age advances. 4. That females are more subject to it than males, possibly on account of the domestic duties keeping them longer exposed to any poisonous influences that may thus arise. (Even the shape of the female garments would favor infection of the generative organs.) 5. That consecutive houses in the same street are found often to be cancer houses, as many of the houses were built at the same time and have a common drain and if it has been badly laid or for any reason becomes faulty the subsoil of several houses may become

sewage contaminated. (A great many of the cancer houses enumerated in this paper have been found to have old disused cesspools, old contaminated wells, or decayed brick sewers lying forgotten in the soil beneath the house.) 6. That a large percentage of these cancer houses (17 per cent.) are end houses of rows, corner houses of streets, or houses on either side of court entrances, as these are places where any defect in a drain would be most likely to be severely affected by sewage. 7. That the older houses are more subject to become cancerous than the modern ones, as the drains in the earlier days were not laid with the care they now are, that glazed pipes were not known and brick drains were often used and the drains were often run under the dwellings, which would after a time decay, become leaky, and thus contaminate the subsoil. 8. That the houses which are built on a porous subsoil, such as sandstone, gravel, etc., are more likely to become cancerous than those built on clay, though the latter in time will become saturated with sewage matter."

6. **Ocular Pain.**—Ocular pain is an invaluable symptom, as Dunn points out, and its absence in inflammatory conditions of the eye may be, as a rule, considered as a favorable sign. Very little pain occurs in connection with conjunctival affections, but the cornea is especially sensitive and this symptom may be a very important guide in suggesting corneal disease where the lesion is minute. In all cases of doubt the corneal surface should be carefully inspected through a lens. Photophobia is explained as due to exposure by minute ulceration, etc., of the corneal plexus. Iritis is not always accompanied with pain and the amount of pain is not always an indication of the severity of the attack, but when the inflammation extends to and involves the ciliary body a distinct tenderness of the globe on palpation is present. In the different forms of iritis the pain symptoms vary. In syphilitic iritis it is very variable, but generally persistent. In rheumatic iritis it is usually present in marked degree, but chiefly in the nighttime. In syphilitic iritis the pain when once relieved does not recur and the most effective treatment in the acute case is local abstraction of blood by means of leeches on the temple of the affected side. In the rheumatic form the pain is of neuralgic character, differing from the throbbing inflammatory type in syphilis and its subsidence is generally the first indication that the attack is passing off. Dry heat is the best application in this class and nothing acts so well as the old-fashioned bran poultice. Leeches are not necessary nor are sedative drugs. Pain in the atrophied globe implies the immediate necessity of enucleation whether there be danger of sympathetic ophthalmia or not. In glaucoma the pain is not due simply, he thinks, to stretching of the sclera, but he suggests that it is due to the compression to which the ciliary processes are subject during the attack, where the only treatment, of course, is iridectomy.

9. **Appendicitis.**—Battle has come to the conclusion from his later experience that the removal of the appendix is always advisable as a security against recurrences. He makes but one exception to the rule and that is when it is not possible or advisable to remove it when the abscess is opened because it has sloughed off and is left free in the pus or comes away.

10. **Izal.**—Summarizing his experience and observations with izal (one of the cresol preparations) Tunnicliffe remarks that "it may be said that so long as the individual differences in cases of phthisis remain so manifold so long must we greet any addition to our non-irritating antiseptics with thankfulness. Of the efficiency of carbonate of guaiacol in certain cases nobody with any experience of it can have any reasonable doubt. The expense, however, of a prolonged treatment with this drug in many cases absolutely contra-indicates it. In spite of many requests from the profession the makers have been unable to reduce materially its price. Some few years ago, in conjunction with Dr. T. H. Arnold Chaplin, the author introduced guaiacolate of piperidin in phthisis, but this, although possessing certain advantages, is also necessarily relatively expensive. In izal we appear to have a cheap and efficacious drug. The best results are to be obtained with it in cases of active pulmonary tuberculosis and of old cavities with

abundant fetid expectoration. According to my experience it seems to exert a beneficial influence in cases in which diarrhea is present, whether this be due merely to decomposition of the intestinal contents or to actual tuberculous lesion of the intestine. In those cases in which the bronchitic element is well marked it is, as was *a priori* to be expected, less useful."

11. **Pernicious Anemia.**—McPhedran says the probable cause of pernicious anemia is a toxin of gastro-intestinal origin. In the largest proportion of cases, with few if any exceptions, there is at some time a history of diarrhea and vomiting. Hunter's theory of the dental origin is briefly mentioned and he has notes in 17 out of his 22 cases of the condition of the teeth. In nearly all they were too well cared for to be a possible source of infection to the stomach. He therefore discredits this as a cause. In no case of the whole 22 was there any apparent cause evident. He calls attention to the fact that the disorder is not progressive but remittent. Many cases run a mild course, but remissions occur in nearly all. While arsenic has been discredited as a remedy in late years, the only case of complete recovery that he had was apparently due to its action. His experience with gastro-intestinal antiseptics has not been specially favorable. He has had some good results apparently from normal saline solution administered hypodermically, but the pain is a drawback. The rectal administration should be as effective, but is often barred by the diarrhea. In two cases there was some apparent benefit from antidiphtheric serum, but it was possibly a *post hoc* rather than a *propter hoc* result. In the more recent cases he has advised moderate purgation while internal intestinal antiseptics and general remedies as arsenic, strychnin, iron, etc., but the results have been also disappointing.

13. **School Hygiene.**—Tidey's article is interesting on account of the facts that he gives in regard to the schools of France, Italy, Belgium, Germany and Switzerland. He speaks very highly of the progress in Switzerland, as well as Belgium and Germany, while in Italy it is to some extent embarrassed by the antiquity of the buildings employed. In France he thinks even the more recent school buildings are not quite up to the mark.

21. **Treatment of Cancer.**—A communication to the Academy from Dr. Lucien Le Roy, of Paris, reports a case of cancer of the lung cured in a few days by the simultaneous administration of arsenic and quinin. The patient was a woman of 57, and he administered 50 cg. a day of hydro-chloro-sulphate of quinin taken at meal times, supplemented by the injection every other day of 5 cg. of sodium cacodylate. Observation of this patient and of another who had a cancer develop in a wen on the scalp, and the observation of others, have convinced him that the only chance of successful inoculation of animals with cancer is on the condition that the inoculation be made in a tissue previously inflamed or altered in its constitution, as in case of lupus or a tuberculous cavity in man. He is now carrying on experimental researches at the official veterinary college at Alford to test the truth of this assumption, assisted by two of the professors.

24. **Early Diagnosis of Typhoid Fever by Bacilli in Blood.**—Courmont examined the blood of nine patients with typhoid fever and found Eberth's bacillus in the blood in every case, sometimes as early as the fifth day of the disease. He had no opportunity to inspect the blood before the fifth day in any instance. He found that there was no apparent connection between the presence of the bacilli in the blood and the agglutinating reaction. He mixed 2 to 4 c.c. of freshly drawn blood with 300 to 500 c.c. of bouillon, shaking the fluid at the end of twenty-four hours if it was not already turbid. He found that the results were always positive with a large amount like this, while they proved negative in 79 per cent. of the control tests with only 20 c.c. of bouillon.

26. **Appendicitic Symptoms in the Course of Certain Infectious Diseases.**—Simonin investigated 506 patients in various infectious diseases and found symptoms on the part of the appendix in 6.33 per cent. of the cases of scarlet fever, 5

per cent. in mumps, 3.7 per cent. in erysipelas, and 2.37 per cent. in throat affections, averaging 3.63 per cent. of the total of 506 patients. When the appendix is sensitive to pressure for eight to ten days, the pain sharp and localized exactly at the spot, it can only be explained by a slight inflammatory reaction of the submucous follicles of the appendix, a latent catarrhal appendicitis.

**27. Antiquity of Rachitis.**—Delpuch published a couple of years ago a historical study of gout and rheumatism through the ages. He had been making a similar study of rachitis just before his death. He found data in art and philology to convince him that rachitis could be traced back to the very dawn of civilization.

**28. Re-Education of the Trunk in Tabes.**—Constensoux has charge of the re-education of tabetic patients at the Salpêtrière, and states that each patient has to be carefully studied in order to learn which muscles are defective, to institute appropriate treatment. The most important part of the task is to train the muscles of the trunk to balance it on the legs. The legs are easily taught to resume their function but the re-education of the trunk is more difficult, and to this cause is due the failures of those physicians who have not derived benefit from systematic exercises to re-educate the muscles of their tabetic patients.

**29. Indications for Treatment with Phosphoric Acid.**—Martinet describes a number of cases to support his assertion that hypo-acidity of the urine, accompanied by an abnormally large amount of phosphates, is frequently the index of hyperchlorhydria in the stomach. On the other hand, hyper-acidity of the urine and abnormally small proportion of phosphates suggest hypo-acidity in the stomach, with hypo-acid dyspepsia, stasis of the food, acid fermentation, etc. In such cases the administration of phosphoric acid may promote digestion and check the acid fermentations by its enuaptic and antiseptic action and by this means restore normal acidity to the urine, paradoxical as this may appear. When, therefore, the proportion of the acidity of the urine to the phosphoric acid is below 1/3, phosphoric acid is contra-indicated on account of the probability of gastric hyperchlorhydria. When the proportion is above 2/5, hypochlorhydric dyspepsia probably exists, with stagnation of the stomach contents and acid fermentations. In such cases phosphoric acid may render signal service.

**30. Alteration of the Liver from Renal Impermeability.**—Gouget reports that experimentation has confirmed the data of the clinic, as he illustrates, in detail, showing that the retention of the poisons of the urine causes certain alterations in the liver and that they are principally, if not exclusively, the work of the urea. The lesions in the liver induced by clinical and experimental uremia are identical with those produced by urea alone. The other organs are more or less affected, but the liver bears the brunt. The insufficiency of its multiple functions, especially of its antitoxic function, has a most important influence on the evolution of the uremia, similar to that of insufficiency of the kidneys in severe icterus. As urea is so little toxic in itself, Gouget is inclined to believe that the deleterious effects are due to the elevated molecular concentration of the plasma. In other words, they are not so much of a chemical as of a physical nature. Increase in the osmotic tension has been shown to be a factor in the genesis of disturbances resulting from impermeability of the kidneys. Voit and others have established the injurious action of the accumulation of even non-toxic substances in the blood. The identity of the symptoms induced in these latter experiments indicates a common origin for them, which may be the increased osmotic tension, from dehydration of the tissues, analogous to what happens in cholera. Gouget is engaged in further research to elucidate this point.

**31. To Separate the Urine from the Ureters.**—Luys has modified the Harris urine separator described in THE JOURNAL of Jan. 29, 1898, and submits his instrument as a simple and convenient method of obtaining the urine from each ureter separately, without catheterization. Harris' instrument is ap-

plied to the roof of the bladder, Luys' to the floor. It consists of two catheters with a metal piece between, the same size and shape as the outline of the catheters. There is a hole at the tip in which a fine chain is fastened and the whole is encased in a loose rubber sheath. The two catheters and the intermediate piece form one instrument when the handle is screwed on. It is inserted along the lower wall of the bladder, which it pushes along and against the flattened rectum. By pulling on the chain, the rubber sheath in the center is drawn up and stretched like a curtain, walling off the two sides of the bladder. As the urine drops from one ureter the suction of an exhaust bulb draws it into the perforations in the corresponding catheter, as in Harris' instrument, connected with a corresponding vial for the urine from each side. The rubber curtain extends upward and also presses against the floor of the bladder below so that no intermixture of the urine from the two ureters is possible.

**35. The Blood in Consumptives.**—Appelbaum states that the blood of a consumptive becomes altered when it is long under the toxic influence of the disease. The amount of hemoglobin diminishes, also the number of corpuscles, and the specific gravity drops. In the second stage of the disease there is liable to be a deceptive improvement—the composition of the blood returns apparently to normal. This is probably merely a concentration of the blood from the loss of water in the night sweats, diarrhea and copious salivary and bronchial secretions. This concentration of the blood is shown in the brighter red of the lips and cheeks. The third stage of phthisis is characterized by a leucocytosis. Neutrophile polynuclear cells form 84 to 86 per cent. of all the white corpuscles, and they are probably derived from the mononuclears. The appearance of numerous transitional forms in the blood heralds the approach of a polynuclear leucocytosis. The alterations in the blood in tall, thin, pale, predisposed subjects frequently long precede other physical or bacteriologic signs of incipient tuberculosis.

**36. Experimental Cholecystitis and Cholangitis.**—Ehret packed the gall-bladder with glass balls or wads of cotton in his experiments on eleven dogs. After an interval of apparent health the animals suddenly exhibited symptoms of cholecystitis or cholangitis. The infection was more severe and more constant in the experiments with the cotton wads. One or more of the wads worked down into the biliary passages. The germs causing the infection were probably of auto-infectious origin, derived from the intestines. These experiments show how a person can tolerate gallstones for a long time without symptoms, and suddenly violent infection may develop. They also show that foreign bodies cause less disturbance in the gall-bladder than when they are in the biliary passages. Violent suppurating infection followed in every instance the passage of a wad into the common bile duct, but the glass balls have remained in the gall-bladder without causing the slightest apparent disturbance in two of the dogs to date.

**37. Treatment of Sciatica.**—Hoelscher has been very successful in treating sciatica in the last ten years by applying a gauze tampon, impregnated with a 5 per cent. solution of carbolic acid, directly to the nerve. The cure is prompt and permanent. He has had only 2 recurrences in 15 cases thus treated, and in these patients the technique was not complete. He leaves the tampon for three or more days, suturing the wound partially over it, and protecting the vicinity by working a moist compress in around it. The patient was able to move his leg without pain as soon as he awoke from the chloroform narcosis, but although the sciatic pain was banished, the patients sometimes complained of pains in the knee or thigh for a few days or possibly some relics of the sciatic pain were experienced requiring renewal of the tampon. The wound healed with suppuration but no other complications were noted and all the pain was definitely abolished after the first few days. The nerve appeared sound to the eye, but in some cases adhesions between the muscles must have compressed the nerve against the bone when the limb was moved, which may have co-operated in the production of the sciatica. There was no spinal affection in any of the cases.

**38. Food Value of Gelatin.**—In order to thoroughly test the nutritional value of gelatin, Brat found it advisable to prepare it in some form which would not become solid as it cooled. He accomplished this by submitting gelatin for several hours to the action of acids at a high temperature. The acids were then neutralized and the dialyzed or filtered product was ground into a powder which he calls "gluton." It dissolves readily in water and does not harden even in cold, concentrated solutions. When added to fluid or solid food it alters the taste so little as to be imperceptible and makes palatable lemonades, etc. The metabolism in four patients at von Leyden's clinic was carefully watched during four to seven days before the gluton was administered and during a similar period during and after the tests. The results confirm Voit's assertions that of all the articles of food which contain nitrogen, gelatin is the one most completely consumed in the body. Experiments on animals corroborated the clinical experiences and indicate that this variety of gelatin is utilized the same as the ordinary kind. It may prove useful as a substitute for the carbohydrates in diabetes, obesity, etc., to assist in controlling hemorrhage and be especially valuable in all diseases requiring a fluid *a.c.*

**39. Stain Analysis of Prepared Foods.**—Weissbein states that analysis by staining is an important means of determining the composition of foods, etc. It supplements and completes chemical analysis and clinical observation. All that is necessary is a centrifugalizer and microscope and either Ehrlich's or Pappenheim's panoptic triacid stain. The results of the stain show the exact proportion and kind of albumin in the preparation, whether it occurs in the form of an albuminate or nucleo-albuminate, whether the starch is unmodified or dextrinized, and whether gluten or less digestible particles are present. We learn also that a large percentage of nitrogen determined by chemical analysis does not always represent a high nutritional value and large proportion of albumin. The stain reveals also the presence of minute particles of the hulls and indigestible substances, which are frequently encased in indigestible cellulose.

**40. Post-Dysenteric Affections.**—Haasler's article is based on observation or dissection of hundreds of cases of dysentery (Ruhr) at Tientsin. Death was usually the result of the destruction of the mucous membrane of the intestines, the functional loss of almost the entire large intestine, or to various complications, especially hemorrhages and peritonitis. His experience indicates that injections should not be used during the ulcerating stage, or only with extreme caution. The site and multiplicity of dysenteric liver and spleen abscesses render them inoperable in most cases. The frequent participation of the appendix in the morbid process threatens appendicitis after recovery from the dysentery, and stenosis and kinking of the intestines are liable to follow later. Encapsulated abscesses may linger and prove the source of recurrence. The organs of respiration frequently participate also in the affection and pleurisy is common, but on the other hand, heart and kidney affections seldom develop as a post-dysenteric affection.

**42. Simple Bedside Test of Urine.**—Bychowsk states that even as little as one or two drops of urine will impart an opalescence to a glass of clean hot water in case of the presence of albumin. The glass must be held against a dark background, such as a black sleeve, and the opalescence spreads through the fluid as the glass is shaken, like the smoke from a cigar. The phosphates produce the same phenomenon, but error from this cause can be prevented by adding a few drops of acetic acid.

**43. Improved Light Generators for Phototherapy.**—Bang, Finsen and Strebel each contribute an article on this subject. Finsen endorses the great efficacy of Bang's metal electrode lamp, described in *THE JOURNAL*, xxxvii, p. 1073. It differs from all lamps hitherto constructed as the optic effect is disregarded and the ultra-violet rays are produced in exceptional abundance, but its effect does not penetrate beneath the surface. The lamp has a very powerful bactericidal action, killing a superficial culture of the staphylococcus in as many

seconds as the arc light requires minutes. Although it is so effective and convenient for action on the surface, Finsen's apparatus still retains its supremacy for deep lesions. Finsen states that Bang's iron electrode generates actually a new kind of light and will probably aid in our better knowledge of the therapeutic action of light and specialize or differentiate the action of light in the treatment of skin diseases. Strebel describes improvements in his lamp, which is constructed somewhat on the same principle as Bang's, but generates blue and violet as well as ultra-violet rays and has thus both a superficial and a deep action. By a combination of a glass rod to conduct the light and a system of reflectors to reflect it into an endoscope tube, he is able to send the light into the male and female urethra and into the uterus.

**46. Diagnostic Value of Certain Alterations in the Eye in General Diseases.**—Litten some years ago called attention to white specks appearing close to the papilla which he had noticed in 80 per cent. of 35 cases of septicemia or malignant endocarditis, all fatal. Further experience has shown that the phenomenon occurs in only about 40 per cent. and that retrogression of the specks and recovery of the patient is possible. When it occurs it is extremely valuable for the differentiation of acute septicemia and malignant endocarditis in their early stages. The specks were always found in the same layer of the retina and at the same distance from the entering point of the optic nerve. They look like round or oval tumors imbedded in the layer of nerve fibers. They have no decided structure; they never break through into another layer of the retina; they form with great rapidity and may vanish without leaving a trace, and are probably a rapidly coagulating exudation of lymph. He has never found them except in cases of septicemia, leukemia, pernicious anemia and scorbutus, although he has sought for them with special care in typhoid fever, etc. In case of a differential diagnosis between septicemia and typhoid fever, therefore, their presence speaks for the former. Most cases of acute miliary tuberculosis can be differentiated by the tubercles in the choroid. In their absence it may be difficult to differentiate it from septicemia as the white specks do not always occur in the latter. Multiple hemorrhages in the fundus of the eye are observed in certain cases of either affection. If the lungs are entirely negative, the evidence is in favor of septicemia. These hemorrhages are also observed in some cases of tubercular meningitis, but there is almost always an accompanying papillitis, which Litten has never seen in septicemia. He has observed three cases of typhoid fever in which a large hemorrhage occurred in the retina with amaurotic symptoms, quite different from the small circumscribed hemorrhages observed in some cases of septicemia. In one of the cases the lesions retrogressed during recovery, but recurred again during a recurrence of the typhoid fever, which he was able to diagnose from the aspect of the eye alone, before the temperature curve or any other symptom differentiated the disease.

**48. Intestinal Tuberculosis and Amyloid Degeneration at Autopsies.**—Zahn has had sections made of the cadavers of consumptives during the last twenty-five years by his students at Geneva, and has paid special attention to primary and secondary intestinal tuberculosis and to amyloid degeneration. The Path. Institute had 6320 autopsies during this period and tuberculosis had been diagnosed in 2058 or 32.56 per cent. The majority were men. Primary intestinal tuberculosis was rarely found, but secondary infection of the intestines was noted in 63.21 per cent. of all ulcerative tuberculous lesions in the lungs, nearly twice as frequent in men as in women. He believes that this secondary infection in the intestines is due to the swallowing of infectious sputa, consciously or unconsciously during sleep. The question is, why do any escape? He attributes the immunity of the comparatively large number free from this complication, to the good functioning of their stomachs. He noted that gastric disturbances or lesions were common in the subjects with secondary intestinal infection. The anatomic lesions predominated in men, the functional in women. This insufficiency of the stomach allowed the tubercle bacilli to pass through the stomach unharmed and infect the

intestines. The conclusion imposes itself that the care of the stomach is one of the most important indications in tuberculosis to prevent this secondary infection. The coincidence of tuberculosis and carcinoma was noted in 3.69 per cent. of all the cases of tuberculosis, and of tuberculosis and sarcoma in 6 cases. Amyloid degeneration was observed in only 105 cases, that is, in 1.66 per cent. It occurred with florid tuberculosis in 98 cases; the lesions were in the lungs in 79 and in the bones in 19. It was found in 7 cases in which there had been no tuberculosis. This rarity of amyloid degeneration he attributes to the lack of extreme poverty in Geneva and its vicinity.

49. **Langerhans' Islands and Diabetes.**—Schmidt has examined the pancreas in 23 autopsies of diabetics. He found it intact in 8, and only slightly altered in 7. In one case the pancreas of a diabetic woman, 62 years of age, proved sound in every respect except the Langerhans' islands. They were nearly all in a state of hyaline degeneration. Opie has described a similar case. In the case of a child of 10 he found an almost isolated, acute interstitial inflammation of these islands. The child had exhibited 6.8 per cent. sugar. Two other cases belonged to the group of chronic interstitial pancreatitis, both of the intralobular or interacinous form, with sclerosis of the islands. In 2 other cases the islands seemed to be intact inside a fibrous capsule while the remainder of the pancreas was the seat of the morbid process. The islands seemed to be constantly regenerating, but whether the new-formed ones are as functionally capable as under normal conditions is open to question.

55. **Etiology of Acute Hemorrhagic Encephalitis.**—Strüssler describes 2 typical cases of this affection with the autopsies. He compares the findings with those observed by others in acute, fatal psychoses, and emphasizes the fact that the clinical picture is practically identical in all, and all were distinguished by coprostitis, and by symptoms indicating hyperemia of the brain and its membranes. The course of events indicated that the hyperemia was the consequence of the coprostitis, due to the toxic action of substances absorbed from the intestines. A number of writers have attributed acute mania to an acute, hemorrhagic encephalitis demonstrated at the autopsy. The connection between hemorrhagic diseases and intestinal auto-intoxication has been established beyond question. Disturbances in the alimentary canal are an almost constant accompaniment of encephalitis. Instances have been known of its succeeding to gastritis.

56. **Tests of Jez's Antityphoid Extract.**—Markl reports comparative tests of Jez's extract and of antityphoid serum on a hundred rabbits and guinea-pigs, more or less. He found that the serum of animals thus treated contained a specific protecting substance or substances not found in normal animals. Their action is anti-infectious, not antitoxic.

58. **Sero-therapy of Tuberculosis.**—Cioli reports experiments with guinea-pigs, inoculating them with tuberculosis and then treating them with Maragliano's anti-tuberculosis serum. None of the animals thus treated died. He also describes several cases of patients so improved as to be practically cured. He points out that it is effective only against the tuberculosis and is contra-indicated in secondary infections.

## Queries and Minor Notes.

### PREGNANCY AND CONTRACTED PELVIS.

FLA., Jan. 23, 1902.

To the Editor:—Please tell me what is the right thing to do in the following case: Mrs. R. is two months pregnant, with contracted pelvis. A previous pregnancy was terminated by bringing on labor at the fifth month; it was found necessary to dismember the fetus and bring it away piecemeal. I have urged and insisted on waiting to term and then having a Cesarean section made with removal of ovaries and uterus. But both Mr. and Mrs. R. reject the idea as too dangerous and too expensive, as they are in straightened circumstances and are at a great distance from anyone I could recommend them to for so serious an operation. This is the first case in my twenty-one years' experience where I have been tempted to produce premature labor, or, rather, abortion, but

the people are poor and there is no other physician within many miles at present. What is the right thing for me to do? If an abortion is performed now, it will doubtless mean a repetition of the same thing every few months, which, of course, I could not countenance. I have not used a pelvimeter, but the bony outlet of the pelvis is so contracted as to make a digital examination difficult.

Ans.—The case is evidently one of contraction of the pelvis of the highest degree, and therefore furnishes an absolute indication for Cesarean section if the pregnancy is allowed to continue. In the management of these cases there is some difference of opinion among authorities, some refusing to sanction any mutilating operation on a living fetus under any circumstances. The majority admit, however, that such operations are sometimes justifiable. If a woman comes to labor in ignorance of her pelvic deformity it may be admitted that she and her husband have some right to decide whether she shall be subjected to a more dangerous operation for the sake of the child, or whether the child shall be destroyed to avoid the risk of a section. In such a case if the woman is in no danger from infection and the child is still in good condition, Cesarean section is indicated. If, on account of a neglected labor, the woman is in danger of infection or the child undoubtedly weakened as a result of the uterine contractions, there is more reason to perforate and remove the child. The case in question, however, undoubtedly differs from those just alluded to in the fact that this patient became pregnant a second time after she knew from her previous experience, and also undoubtedly from the counsel of her physician, that she could not bear a living child. Her right to a choice in the conduct of the case is undoubtedly much lessened thereby. When a patient presents herself, no matter what the previous history, she must be given the best advice and treatment. Sometimes this is not accepted, and we must be content with an alternative. There is no doubt, however, that the management you suggested is proper, and it should be urged with all possible force. There should be practically no risk in the operation, because it would be provided for beforehand, and done with all possible care. It would be a less dangerous operation than the great majority of the hundreds of laparotomies that are done every day. This fact should be impressed upon the minds of the woman and her husband. It should be possible to meet the expense of such an operation. The woman should go to a hospital where she could have the gratuitous services of a competent abdominal surgeon. Transportation for even two or three hundred miles with a moderate hospital fee would be but little more than ought to be paid for inducing abortion at her home. Forcible presentation of all the advantages of Cesarean section, removal of groundless fears and objections, presentation of the danger of inducing abortion and of future danger to which the woman would be subjected through probable future pregnancies, should lead to a right decision in the case. Finally, abortion should not be resorted to without first calling in consultation.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**A MANUAL OF PRACTICAL ANATOMY.** By the late Alfred W. Hughes, M.B., M.C. Edin., F.R.C.S. Edin., etc., Professor of Anatomy, King's College, London. Edited and completed by Arthur Keith, M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy, London Hospital Medical College, etc. In Three Parts. Part I. The Upper and Lower Extremities. Illustrated by 38 Colored Plates and 116 Figures in the Text. Cloth. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**A MANUAL OF CLINICAL DIAGNOSIS BY MEANS OF MICROSCOPICAL AND CHEMICAL METHODS FOR STUDENTS, HOSPITAL PHYSICIANS AND PRACTITIONERS.** By Charles E. Simon, M.D., author of Simon's Physiological Chemistry, etc. New (4th) Edition, Thoroughly Revised and Enlarged. In One Handsome Octavo Volume of 608 Pages, Illustrated with 139 Engravings and 19 Plates in Colors. Cloth. Price, \$3.75 net. Philadelphia and New York: Lea Brothers & Co. 1902.

**A GUIDE TO THE MICROSCOPIC EXAMINATION OF THE EYE.** By Prof. R. Greeff, Surgeon to the Ophthalmic Department of the Royal Charité Hospital, Berlin. Translated from the Second German Edition by Hugh Walker, M.A., M.B., C.M., Assistant Surgeon and Pathologist to the Ophthalmic Department of the Glasgow Royal Infirmary. Cloth. Pp. 171. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1902.

**A RETROSPECT OF SURGERY DURING THE PAST CENTURY.** Being the Hunterian Oration of the Hunterian Society, 1901. By John Poland, F.R.C.S., Surgeon to the City Orthopedic Hospital. Cloth. Pp. 97. London: Smith, Elder & Co. 1901.

**TRANSACTIONS OF THE TWELFTH ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF WASHINGTON.** Held at Seattle, June 18, 19, 20, 1901. Cloth. Pp. 259. Spokane: Shaw & Borden Co. 1901.

**ROUGH NOTES ON REMEDIES.** By Wm. Murray, M.D., F.R.C.P. Lond., Newcastle-on-Tyne. Fourth Edition. Cloth. Pp. 176. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1901.

**THE SOCIETY OF THE LYING-IN HOSPITAL OF THE CITY OF NEW YORK.** Annual Report of 1903d Year, from October 1, 1900, to Sep-

tember 30, 1901. Paper. Pp. 126. Printed by Order of the Board of Governors.

TRANSACTIONS OF THE THIRD ANNUAL SESSION OF THE TRI-STATE MEDICAL ASSOCIATION OF THE CAROLINAS AND VIRGINIA, Held at the Jefferson Hotel, Richmond, Va., Feb. 26 and 27, 1901. Cloth. Pp. 237. Raleigh: Edwards & Broughton. 1901.

THIRTY-FIRST ANNUAL REPORT OF THE CENTRAL STATE HOSPITAL OF VIRGINIA (Petersburg, Va.), for the Fiscal Year Ending Sept. 30, 1901. Paper. Pp. 126. Richmond: O. E. Flanhart Printing Co. 1901.

A CHART OF DISEASES OF THE LUNGS, PLEURAE, BRONCHII, TRACHEA AND LARYNX. By Edward C. Hill, M.D. Published by the McArthur Hypophosphite Co., Ansonia, Conn.

TRANSACTIONS OF THE BERKS COUNTY MEDICAL SOCIETY, for the Year 1901. Volume VI. Paper. Pp. 99. Reading, Pa.: Norton Printing House. 1901.

SUMMARY OF THE ANNUAL REPORT of the Library Committee of the College of Physicians of Philadelphia, for the Year 1901. Paper. Pp. 4.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., January 16 to 22, 1902, inclusive:

Amos W. Barber, contract surgeon, member of a board at Fort D. A. Russell, Wyo., to examine officers of the Army for promotion.

Edmund Barry, contract surgeon, from duty at the General Hospital, Presidio of San Francisco, Cal., to Fort Dade, Fla., for duty at that post.

James R. Church, lieutenant and asst.-surgeon, U. S. A., on the expiration of his present sick leave, to report for duty to the commanding officer of the General Hospital, at Washington Barracks, D. C.

Walter Cox, lieutenant, asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., whence he will report by telegraph to the Surgeon-General of the Army for instructions.

Louis W. Crampton, major and surgeon, U. S. A., leave of absence for two months granted, on the expiration of which he will report for duty at Fort Adams, R. I.

William F. Lewis, captain and asst.-surgeon, U. S. A., member of a board at Fort D. A. Russell, Wyo., to examine officers of the Army for promotion.

Walter D. McCaw, major and surgeon, U. S. A., leave of absence for one month granted, on the expiration of which he will report for duty at Fort Wadsworth, N. Y.

Edward W. Pinkham, lieutenant, asst.-surgeon, U. S. A., leave of absence for three months, with permission to go beyond sea, granted.

Irving W. Rand, captain, asst.-surgeon, U. S. A., from Fort Trumbull, Conn., to duty at Fort Hamilton, N. Y.

Edwin W. Rich, lieutenant and asst.-surgeon, U. S. A., from Fort Totten, N. Y., to San Francisco, Cal., en route for service in the Division of the Philippines.

Joseph L. Sanford, contract surgeon, from Clifton, Va., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Joseph J. Shafer, contract surgeon, from Fort Dade, Fla., to his home, Atlanta, Ga., for annulment of contract.

Herbert M. Smith, lieutenant and asst.-surgeon, U. S. A., from Fort Leavenworth, Kan., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Guy Stone, contract surgeon, from temporary duty at the General Hospital, Presidio of San Francisco, Cal., to his home, Nashville, Tenn., for annulment of contract.

Harry H. Van Kirk, contract surgeon, now at Sunbury, Ohio, is relieved from further duty in the Division of the Philippines and will proceed to Fort Leavenworth, Kan., for duty.

Walter D. Webb, lieutenant and asst.-surgeon, U. S. A., relieved from further duty in the Division of the Philippines and assigned to duty at Fort Totten, N. Y.

Marlborough C. Wyeth, major and surgeon, U. S. A., from the medical supply depot, Havana, Cuba, to duty at Fort Trumbull, Conn.

### Appointments, Promotions, Retirements, Etc.,

of medical officers recorded in the Adjutant-General's Office, Washington, D. C., between Dec. 15, 1901, and Jan. 15, 1902:

*Regular Army, Retirements*—Colonel Dallas Bache, asst. surgeon-general, Jan. 1, 1902, at his own request, after forty years' service, act of June 30, 1882. Colonel Charles R. Greenleaf, asst. surgeon-general, Jan. 1, 1902, by operation of law, act of June 30, 1882.

*Volunteers, Honorably Discharged*—Major William F. Lippitt, Jr., surgeon, Dec. 31, 1901. Captain Vernon J. Hooper, asst.-surgeon, Dec. 31, 1901.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ended January 25:

Surgeon D. O. Lewis, ordered to the *Pensacola*.

P. A. Surgeon J. E. Page, detached from the *Pensacola*, and ordered to be ready for sea duty.

Rear Admiral W. K. Van Reypen, Surgeon-General of the Navy, retired from active service, January 25, upon his own application, after 40 years' service; with the rank and three-fourths the sea pay of the next higher grade.

Medical Inspector W. A. McClurg, ordered to the *Olympia*, January 25.

P. A. Surgeon E. O. Huntington, commissioned P. A. Surgeon from May 24, 1901.

P. A. Surgeon J. B. Dennis, commissioned P. A. Surgeon from May 25, 1901.

Asst.-Surgeon E. G. Parker, ordered to the *Pensacola*.

Asst.-Surgeon U. R. Webb, detached from the *Pensacola*, and or-

dered to the Asiatic Station, sailing from San Francisco, February 7.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 23, 1902:

Surgeon S. D. Brooks, to proceed to Bath, Maine, for special temporary duty.

Surgeon G. M. Magruder, granted thirty days' leave of absence, on account of sickness, from January 22.

P. A. Surgeon A. R. Thomas, to proceed to Liverpool, England, for special temporary duty.

Asst.-Surgeon J. E. Anderson, upon expiration of leave of absence, to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty.

A. A. Surgeon Felix Garcia, granted leave of absence for 30 days from January 25.

Hospital Steward G. C. Allen, granted leave of absence for two days from January 27.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended January 25, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, Jan. 4-11, 11 cases; San Francisco, Dec. 29-Jan. 12, 10 cases.

Illinois: Belleville, Jan. 11-18, 8 cases; Chicago, Jan. 4-18, 14 cases, 1 death; Freeport, Jan. 4-11, 2 cases; Galesburg, Jan. 11-18, 2 cases.

Indiana: Evansville, Jan. 4-18, 6 cases.

Iowa: Clinton, Jan. 11-18, 3 cases; Ottumwa, Nov. 30-Dec. 28, 79 cases.

Kansas: Wichita, Jan. 11-13, 1 case.

Kentucky: Lexington, Jan. 4-11, 3 cases.

Louisiana: New Orleans, Jan. 4-18, 5 cases, 3 deaths.

Maine: Portland, Jan. 11-18, 2 cases.

Massachusetts: Boston, Jan. 4-18, 76 cases, 9 deaths; Brockton, Jan. 11-18, 1 case; Brookline, Jan. 11-18, 1 case; Cambridge, Jan. 4-11, 3 cases, 1 death; Clinton, Jan. 4-11, 3 cases; Holyoke, Jan. 11-18, 1 case; Lowell, Jan. 11-18, 1 case; Marlboro, Jan. 4-11, 1 case; Medford, Jan. 4-11, 1 case; Quincy, Jan. 4-11, 1 case; Somerville, Jan. 4-11, 2 cases, 1 death; Weymouth, Jan. 4-11, 1 case.

Michigan: Ann Arbor, Dec. 28-Jan. 4, 2 cases; Detroit, Jan. 4-16, 4 cases, 1 death; Grand Rapids, Jan. 11-18, 2 cases.

Minnesota: Wlnona, Dec. 28-Jan. 4, 1 case.

Nebraska: Omaha, Jan. 4-11, 41 cases; South Omaha, Dec. 1-Jan. 18, 216 cases.

New Hampshire: Nashua, Jan. 4-18, 2 cases.

New Jersey: Camden, Jan. 4-18, 31 cases, 6 deaths; Jersey City, Dec. 29-Jan. 19, 43 cases; Newark, Jan. 4-16, 68 cases, 12 deaths; Passaic, Jan. 4-11, 2 cases, 1 death; Plainfield, Jan. 11-18, 4 cases.

New York: Binghamton, Jan. 4-18, 1 case, 1 death; Mount Vernon, Jan. 11-18, 1 case, 1 death; New York, Jan. 4-18, 48 cases, 8 deaths.

Ohio: Cincinnati, Jan. 4-17, 27 cases; Cleveland, Jan. 4-18, 4 cases; Dayton, Jan. 11-18, 1 case; Hamilton, Jan. 11-18, 1 case; Toledo, Jan. 4-18, 4 cases; Youngstown, Dec. 28-Jan. 18, 30 cases, 4 deaths.

Pennsylvania: Allegheny, Jan. 4-11, 1 case; Altoona, Dec. 28-Jan. 4, 4 cases; Lebanon, Jan. 4-11, 1 death; Norristown, Jan. 4-11, 10 cases, 1 death; Philadelphia, Jan. 4-11, 213 cases, 31 deaths; Pittsburg, Jan. 11-19, 4 cases.

Rhode Island: Providence, Jan. 12-18, 1 case.

South Carolina: Greenville, Jan. 4-11, 1 case.

Tennessee: Memphis, Jan. 4-18, 11 cases.

Utah: Salt Lake City, Jan. 11-18, 1 case.

Vermont: Burlington, Jan. 4-11, 38 cases.

Washington: Tacoma, Dec. 29-Jan. 12, 12 cases.

Wisconsin: Green Bay, Jan. 4-18, 25 cases; Milwaukee, Jan. 4-18, 3 cases.

#### SMALLPOX—FOREIGN.

Africa: Monrovia, Dec. 7-14, 1 case.

Austria: Prague, Dec. 14-28, 12 cases.

Brazil: Rio de Janeiro, Dec. 7-22, 77 deaths.

Canada: Halifax, Jan. 4-11, 12 cases; Quebec, Jan. 4-18, 110 cases, 1 death; St. John, Dec. 28-Jan. 18, 3 deaths.

Colombia: Panama, Dec. 23-Jan. 13, 48 cases.

France: Lyons, Dec. 21-28, 1 death; Paris, Dec. 21-Jan. 4, 7 deaths.

Great Britain: Glasgow, Dec. 27-Jan. 10, 31 cases; Liverpool, Dec. 21-Jan. 4, 5 cases; London, Dec. 21-Jan. 4, 1419 cases, 68 deaths; Newcastle-on-Tyne, Dec. 21-28, 1 case; Sheffield, Dec. 21-28, 1 case.

India: Karachi, Dec. 8-15, 6 cases, 2 deaths.

Italy: Naples, Dec. 21-28, 32 cases, 2 deaths.

Russia: Moscow, Dec. 7-21, 34 cases, 12 deaths; Odessa, Dec. 14-28, 11 cases, 2 deaths; St. Petersburg, Dec. 14-28, 11 cases, 4 deaths; Warsaw, Dec. 14-21, 5 deaths.

Spain: Barcelona, Dec. 24-31, 3 deaths; Corunna, Dec. 21-Jan. 4, 2 deaths; Vigo, Dec. 1-31, 1 death.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Dec. 8-22, 2 deaths.

Mexico: Vera Cruz, Dec. 28-Jan. 18, 8 cases, 5 deaths.

#### CHOLERA.

India: Bombay, Dec. 10-17, 2 deaths; Calcutta, Dec. 7-14, 36 deaths; Madras, Dec. 7-13, 5 deaths.

Java: Batavia, Nov. 30-Dec. 7, 10 cases, 4 deaths.

#### PLAGUE.

Brazil: Rio de Janeiro, Dec. 7-22, 13 deaths.

China: Hongkong, Dec. 7-14, 1 case, 1 death.

India: Bombay, Dec. 14-17, 144 deaths; Calcutta, Dec. 7-14, 24 deaths; Karachi, Dec. 8-15, 81 cases, 56 deaths.

Turkey: Smyrna, Dec. 28, 1 case.

### THE PROBLEMS OF SERUM-THERAPY.

JOSEPH McFARLAND, M.D.

Professor of Pathology and Bacteriology in the Medico-Chirurgical  
College.

PHILADELPHIA.

With the advance of our knowledge of immune serums the evidence becomes more and more convincing that they operate chemically to produce their effects. So long as we conceived that their introduction into an animal was succeeded by a general vital reaction by means of which the cells received some kind of invigoration or rejuvenation, the conditions under which the serums operated were so occult that it seemed impossible to attain positive information about them.

The recognition of the chemical nature of the reaction, and the discovery that the laws governing it are not unlike laws governing other reactions with which we are familiar, together with the discovery that the toxin-antitoxin reaction is but one of a large series of vital reactions, has opened the way to new applications of serums in practice, and has suggested entirely new lines of research.

It will be remembered by those who are familiar with the literature and history of serum therapy that the subject had its origin in studies upon immunity. The only form of immunity that suggested itself to the pioneers in the investigations was immunity to the infectious agents—the bacteria. Pasteur was the originator of artificial immunization, and subsequent workers followed closely in his footsteps. The next advance was the production of immunity to the disease-producing products of the bacteria. This was first achieved by Salmon and Smith, and Behring and Kitasato utilized this principle in their researches.

It occurred to Ehrlich that if the toxalbumins of bacteria would cause immunity and the formation of antitoxins, probably other vegetable toxalbumins would do the same and he proved the truth of his conclusion by his experiments with ricin and abrin. The subject of animal poisons was next attacked by Phisalix and Bertrand, and by Calmette, who found that the venoms of poisonous serpents reacted in the same manner. From this time on the subject of toxicology underwent a new development through a great amount of experimental work done in endeavoring to produce immunity to and develop antitoxins for the different animal and vegetable poisons. Very little success was obtained with mineral poisons, the only one of which a successful report is made being arsenic, which Besredka found capable of generating antiarsenine when properly introduced into

the body of rabbits. Having thus worked over the field of poisons very thoroughly, experimenters next turned their attention to other active substances, and Morgenroth discovered that the introduction of rennet into the body of an animal was succeeded by the appearance in the blood of a principle (antirennene) which impeded the action of rennet upon milk. Bordet, and Bordet and Gengou, worked with fibrin ferment, and found that the introduction of fluids rich in this ferment into the body is followed by the occurrence of some substance in the serum by which the coagulation of the blood may be prevented or delayed.

There are thus presented to us a variety of reactive phenomena, more or less closely related to one another in that there occur in response to a similar form of stimulation more or less similar substances.

When we come to study more particularly the nature and conditions of the phenomena, many points of interest at once appear. In rare cases the blood of normal animals manifest a more or less marked degree of the same activity which appears in the blood of animals that have undergone the process of immunization. Why a few animals should present this peculiarity is a problem at the present time unsolved. It may indicate that there are various ways in which the balance of physiological energy can be altered, and that at times other stimuli than artificially introduced toxins, etc., may lead to the generation of serums of phenomenal action. On the other hand, it is, of course, not impossible that the experiment animals have under natural conditions come under influences resembling those to which we subject them experimentally. Thus Cobbett, who has made the most interesting and important observations upon the occasional occurrence of antitoxin in the blood of normal horses, has also observed spontaneous diphtheria in a horse.

Except in these rare cases, however, the appearance of antitoxic, anticoagulant or other phenomenal powers in the blood depends altogether upon the manipulations to which animals have been subjected.

The formation of the bodies takes place through means that are not yet clearly explained, though the "lateral chain" theory of Ehrlich affords a very satisfactory explanation for many of them. This theory presupposes that the stimulating substances introduced into the experiment animal have the power of combining with certain groups of molecules in the protoplasm of certain cells in the body, for which they have affinity. The combination is succeeded by a regeneration of the lateral chains, which appear in a quantity slightly in excess of that existing before the stimulation of combination occurred. When more of the combining substance is now injected into the animal and the combining lateral chains again

consumed, another still more copious regeneration occurs, and so on until the particular lateral chains are present in great excess, pass out of the cells into the blood where is it known to us as antitoxin.

It will be noted that this is a purely chemical theory which implies throughout that the lateral chains and antitoxin are "combining substances."

It may be well to consider the evidences which exist at present to support this chemical theory.

1. The action of antitoxin upon toxin always takes place in fixed proportions, without relation to the quantity employed. Thus, if a certain quantity of antitoxin protects an animal against a certainly fatal dose of any toxin, it is always true that within a small percentage of error, ten times the antitoxin will protect against ten fatal doses, and one hundred times against one hundred fatal doses. So positive is this law of multiples, and so accurate is the result of its continued application, that Ehrlich has made it the basis of his method of testing the value of antitoxins, which are estimated against one hundred fatal doses of toxin.

2. The separation of toxin and antitoxin when once mixed under proper conditions is probably impossible. There are different opinions about this, as Roux made what he supposed to be neutral mixtures of toxin and antitoxin, which produced no symptoms when introduced into certain animals, but which caused local symptoms and even death when introduced into other species of animals. This, he believed, showed that the toxin was not combined with the antitoxin, as it was able to produce death. Cobbett, however, points out that in such a neutral mixture there is always considerable free or unneutralized toxin—less than one fatal dose for that animal for which the mixture is neutral—which may be sufficient to cause the death of a more susceptible animal. At Roux's suggestion Calmette endeavored to separate venom from antivenene with which it had been mixed by the use of a degree of heat which coagulated and precipitated the serum, but did not injure the venom. He found that neutral mixtures when heated became poisonous again. Martin and Cherry, however, showed that Calmette might have had different results if he had permitted the venom and antivenene to remain in contact for a short time at a temperature of 35 C. This allowance for time and temperature was shown to be necessary by Ehrlich, who found that the action of antiricin upon ricin was accelerated by warmth and retarded by cold, and that time was essential to its occurrence. Martin and Cherry found that if the neutral mixtures of venom and antivenene were permitted to stand for a half-hour at 35 C., then heated, the mixture did not again become poisonous.

Filtration has also been employed for the purpose of proving the chemical nature of the reaction. Martin and Cherry found that solutions of venom passed through a porcelain filter coated with gelatin, but that the antivenene, having molecules of larger size, did not pass through. If no chemical action between toxin and antitoxin took place, then when a neutral mixture was filtered, the filtrate should be poisonous. This they found to be untrue. The filtrate from neutral mixtures was harmless. Cobbett repeated these experiments with venom and antivenene, and also with diphtheria toxin and antitoxin, and found the filtrates harmless.

3. The occurrence of the reaction *in vitro* is one of the best proofs that it does not occur through some indirect action of the body cells. It is true that no visible reaction takes place between diphtheria toxin and its antitoxin, between tetanus toxin and its antitoxin, or be-

tween venom and antivenene as ordinarily mixed, but there are reactions that take place in the test-tube under the very eyes of the experimenter that are of the greatest interest and importance.

It has been shown by Kossel that the serum of poisonous eels (many eels have blood poisonous to small mammals) has the property of dissolving the coloring matter out of the red blood corpuscles of rabbits and guinea-pigs. When defibrinated blood of one of these animals is diluted with physiological salt solution and placed in a test-tube; the addition of a certain quantity of eel's serum causes the corpuscles to dissolve. The addition of the serum of an animal immunized to the poisonous action of eel's blood, when added to the blood and eel's serum mixture, entirely inhibits the laking power of the eel's serum, and does so in definite proportions.

Ehrlich found that ricin, when added to defibrinated blood, caused agglutination of the corpuscles which rushed together in clumps, but that the addition of a proper proportion of antiricin entirely inhibited its action in this respect. The reaction he found to be inhibited by cold and accelerated by heat, and to require a certain length of time for its occurrence.

Morgenroth found that the blood of an animal that had received frequent injections of a solution of rennet entirely inhibited the action of rennet upon milk. Carefully estimating the quantity of rennet, the temperature and the time necessary for the occurrence of milk coagulation, he found that the addition of a definite quantity of the antivenene was invariable in its inhibiting influence. Normal serum exerted no influence upon the coagulating power of rennet.

Madsen has given most interesting demonstrations of the effect of the hemolytic principle of tetanus toxin, and the control of its effects upon the blood corpuscles by immune serum. When defibrinated blood is isotonicly diluted with saline solution and placed in a test-tube, the addition of the tetano-lysin is followed by the solution of its pigment. This solvent action is entirely inhibited by the immune serum, though normal serums are powerless to prevent it.

Bordet, and Bordet and Gengou, have succeeded in the production of a body antagonistic to the coagulation of the blood, by the injection of animals with fluids rich in fibrin ferment. They found that a given proportion of this serum would check the coagulation of rabbit's blood to which it was added, and that definite quantities of it were antagonistic to definite quantities of added fibrin ferment.

A most valuable contribution has come from the pen of Ehrlich and Morgenroth, who investigated the solution of blood corpuscles by hemolytic serums. They found that the laking of the blood is by no means a simple matter, but one in which numerous factors are involved.

The chief important factor is what they describe as the *immune body*, and it is through the activity of this that the corpuscles are dissolved. The immune body is however, only able to operate in the presence of another body which is complementary to it, and is called the *addiment*. It is very interesting to note that it makes considerable difference in what order the factors involved in the reaction are brought together, not all combinations of the three essentials—corpuscles, immune body and addiment—being followed by laking.

Mark Richardson, in a paper read before the American Association of Pathologists and Bacteriologists, in Boston, in 1901, has shown how truly this principle applies

in certain diseases for the treatment of which immune serums have thus far been found inadequate. It is well known that highly immune typhoid serums not infrequently cause solution of the specific bacilli. It is, however, an almost universal experience that the injection of such highly immune serums into patients suffering with typhoid fever is not followed by any appreciable amelioration of the symptoms. One would imagine that solution of the bacteria must necessarily follow, but the difficulty seems to be that it is not the immune body, in which the serum is rich, but the complementary body that is needed. This might be supplied with ease, could we find out just what serum best furnishes it, yet its addition might not be followed by the expected result, for the reason that the order of combination is so essential. Thus, Richardson found that the injection of normal serum containing the complementary body did not improve typhoid fever, because the immune body having been preformed in the body, interfered with the necessary primary action of the complementary body upon the bacteria.

Experimenting with bacteria in the hanging drop, he found that if it was true that a mixture of typhoid culture, normal serum and typhoid immune serum produced hemolysis, it was almost certainly not true that typhoid bacilli, immune serum and normal serum would do so, the difference being solely in the order in which the combination took place.

Wassermann also demonstrated the accuracy of Ehrlich's view by his experiments with typhoid infection, and concludes that two separate substances are concerned, one of which kills the bacteria, the other serving to fix its combination with them. To the bactericidal substance he applies the name "end body," that which fixes the combination the "intermediate body." Experimentally he found that normal beef serum was best adapted to the supply of "end body," so that when he inoculated guinea-pigs with three loopfuls of typhoid culture, and after 30 minutes gave them a hypodermic injection of 0.5 c.c. of typhoid immune serum and 4 c.c. of fresh normal beef serum, they recovered, while the control animals which received normal serum, or immune serum alone, all died in 24 hours.

The number of cases reported by men of trained observation, in which the injection of normal serums has been followed by improvement in various diseased conditions, can be in part explained upon the assumption that it supplied to the blood some *intermediate* or *complementary* substance, essential to the proper performance of physiological function, but which is temporarily deficient.

How widespread and important these immune and intermediate bodies may be in our processes it is impossible to say, but the recent observations of Metchnikoff indicate that they have very wide spheres of usefulness.

Metchnikoff found that the introduction of any kind of cellular tissue into the body increases the ability of the blood to act destructively upon that kind of tissue. Thus, if blood of one animal is injected into another, its serum becomes hemolytically active. If comminuted epithelium is introduced, the serum becomes epitheliolytic in its tendencies, etc.

Here we find an entirely new reaction, with an entirely new sphere of usefulness. Unfortunately, it is still too new to predict what may be the value, if any, of this phenomenon in practice. The possibility of thus attacking cancer at once appeals to us. How desirable it would be to produce a serum whose activity would be

to inhibit the growth of epithelium and hasten the destruction of epithelial cells!

However, the lesson that is to be learned from the achievements thus far consummated is that the action of immune serums is far from simple, depends upon many factors with which we are just beginning to become acquainted, and that the failure of our efforts in many directions in the past may simply be referable to our ignorance of how to use materials at hand.

## THE PREVENTION OF PELVIC DISEASE DURING AND AFTER LABOR.\*

J. F. BALDWIN, A.M., M.D.

Surgeon to Grant Hospital; Fellow of the American Association of Obstetricians and Gynecologists, Etc.

COLUMBUS, OHIO.

The prevention of pelvic disease during and after labor consists in the avoidance of infection and traumatism. Infection is frequently the almost necessary result of traumatism, but traumatism without regard to infection is frequently followed by more or less serious pelvic disturbances.

### CLEANLINESS NECESSARY.

During the course of an otherwise normal delivery, the great danger to the mother is from infection carried in from without. No modern physician, I take it, believes in auto-infection, that is, in any infection arising from within the pelvis. A chronic disease of the appendix, or of the appendages, may be lighted up by the process of delivery, but no pelvic disease will be initiated except by infection from without. This infection may be introduced in a variety of ways. The very latest bacteriological investigations have shown conclusively that the secretions of the upper part of the vagina are entirely sterile. It is not until they reach the introitus that they show evidences of contamination. The introduction of the examining finger inevitably carries some of this infection from the vulva into the vagina and up to the cervix. Copulation has the same effect. Many women practice self-examination, and this doubtless accounts for certain otherwise obscure cases of puerperal infection in which the attending physician after his arrival has exercised all due precautions.

Before the introduction into obstetrical work of antiseptics, and later of asepsis, the mortality in lying-in hospitals, where infection was carried from patient to patient, was simply frightful; but with the recognition in these institutions of the sources of danger and the means for their avoidance, the mortality has decreased until now a properly managed hospital is the safest possible place for a woman to be confined, not only as regards mortality, but morbidity. The same is not true, however, in private practice. The investigations of Bacon of Chicago, and of Boxall in England, show conclusively that in general practice, and especially in rural districts, puerperal mortality and morbidity are practically no less than before the days of Lister. It is the general practitioner, therefore, who must improve his methods.

The use of antepartum douches, as recommended some years ago when the vaginal secretions were regarded as infected throughout, is to be unequivocally condemned. These secretions are nature's lubricant and should not be unnecessarily interfered with. If, however, from his knowledge of the case, the physician suspects a gonorrheal infection to be present, then not only should

\* Read in a Symposium on the Prevention of Pelvic Disease, before the Ohio State Medical Society, at Cincinnati, May 9, 1901.

the douches be used, but the vagina should be scrubbed out as thoroughly as before a surgical operation. This cleansing is done not only in the interests of the mother, but in the interests of the child, for the prevention of gonorrheal ophthalmia. In the absence, however, of such known or suspected infection, the special cleansing processes should be limited to the vulva and the region about. If this is done, and the practitioner uses the ordinary precautions as to the cleansing of the hands and instruments, puerperal infection will not take place.

In giving directions as to the cleansing of the hands of the attending physician it is entirely useless to advise any such extremes of asepsis as will not be carried out. These precautions must be limited to such as are feasible and sensible. I have seen explicit directions given requiring at least ten minutes for the scrubbing of the hands with soap and hot water, and then three minutes' continuous soaking in a 1 to 1000 bichlorid solution; or a similar scrubbing of the hands with subsequent treatment with permanganate of potash and oxalic acid. Such precautions are not feasible in general practice and will not be carried out. If the attending physician scrubs his hands thoroughly with hot water and soap, and if his nails are trimmed short and kept clean, he has done all that can reasonably be expected of him. If, however, he has reason to believe that his hands have been infected by contact with other cases, then the more thorough sterilization previously indicated would be required. If, moreover, an obstetrical operation is needed, involving the introduction of the hand into the uterus, as for turning or the removal of secundines, then the most thorough sterilization of the hand and arm is essential, or, better still, the use of the rubber glove and armlet. For the application of forceps the instrument itself should be sterilized by boiling. This, with the thorough washing of the hands, as above indicated, and the cleansing of the vulva will suffice. The finger-nails of the physician are the main source of danger. Many physicians, especially in country practice, are obliged, to a considerable extent at least, to care for their own horses and to do more or less work about the garden. Such men are very apt to have horny hands which in bad weather are quite liable to become more or less chapped and fissured. It is quite impossible to render such hands absolutely sterile. In such cases rubber gloves can not be too highly recommended.

While the presentation and position of the child can be determined under ordinary circumstances and without any special difficulty by external palpation, this procedure conveys no information as to the condition of the cervix or the progress of labor. This latter knowledge may be unimportant in a lying-in hospital, where nurses and internes are always within reach, but it is of prime importance to the general practitioner, whose duties require him to look after other cases than the patient in labor. He makes a vaginal examination and decides whether he must remain or whether he can be at liberty to make other calls for an hour or more. At the end of the period which he had allowed himself, he returns and another examination enables him to determine for the second time whether he can be spared. These examinations are essential and to forbid them is simply visionary. For these cases, rubber gloves, which can be left in an antiseptic solution during the physician's absence, are a very great convenience and of great value, though not absolutely essential.

Postpartum douches, like the antepartum, should not be used in normal cases. The natural downward flow of the lochial discharge prevents infection from reach-

ing the uterus, while the use of the syringe nozzle, even if just sterilized, may carry infection from the vulva to the cervix, and even within it. In case, however, infection takes place and the lochia becomes offensive, then the use of the vaginal douches carefully administered by a skilful nurse is to be commended.

#### REMOVAL OF MEMBRANES.

In case a portion of retained membrane or placenta becomes infected, or causes hemorrhage, it should be at once removed. Here, however, the use of the curette has resulted in great harm. A blind curetting of the endometrium under these circumstances will open up a thousand channels for fresh infection while removing the offending body, although it not infrequently happens that the offending bit of tissue itself may in whole or in part be missed by the curette. Under such circumstances the misdirected instrumentation will be followed by a fresh invasion of sepsis, with perhaps promptly fatal results. For the removal of such retained tissue no instrument is as sure and safe as the sterilized finger of the intelligent physician. Give the patient chloroform, sterilize the vagina by thorough scrubbing, sterilize the hands, and then steadying the uterus from above with one hand, introduce the finger and explore the interior. The finger will find the offending tissue and will almost invariably remove it with ease. In case it is too adherent the curette may then be used directly to the spot and without injury to the rest of the endometrium. Such removal should then be followed by a hot intra-uterine douche, so as to thoroughly wash out debris. This douching should be done by the physician himself, and once is sufficient if the preceding removal has been thorough.

#### TRAUMATISMS.

An overlooked laceration of the perineum, even if the laceration be very slight, furnishes a point for puerperal infection. A lacerated cervix rests in the sterile region of the vagina, but a lacerated perineum is in the region constantly exposed to infection. This exposed surface is promptly removed by an immediate operation. There is no excuse for a failure to detect this injury, since an examination under the eye should be made in every case, nor is there any excuse for failure to close the laceration immediately, since the materials for so doing are in every house. It may be more convenient and look a little more professional for a practitioner to have with him silkworm gut, special needles and needle forceps, but these are entirely inessential. A small darning needle, or a heavy sewing needle, with its temper removed through the center by heating so that it can be somewhat bent; silk, which can be found in nearly every house, or even cotton or linen, hair from the horse's tail, or even a cow's tail for that matter, all these are everywhere available, can be promptly sterilized by boiling and will answer just as good a practical purpose as anything that can be found.

Lack of assistants and of suitable light and instruments render it undesirable to attempt an immediate operation on a lacerated cervix; while the fact that this cervix is in the sterile zone and will very likely heal satisfactorily without further attention, renders its closure of little importance. A laceration, however, involving the vagina and perineum belongs to an entirely different category, for reasons which I have stated, and these lacerations therefore should be repaired either at once or within twenty-four hours.

It will, of course, be useless to cleanse the vulva preceding examinations if the sheets and dressings which

are to come in contact with the cleansed surfaces are dirty. In most houses when labor begins the resources of the ragbag are drawn upon for the construction of an absorbent pad to be placed under the hips of the parturient. If the rags from these sources are clean nothing more can be asked for, but ordinarily their condition is the reverse; hence the attendant should insist upon a sufficient supply of clean sheets, towels, pillow slips, or something of the sort, to secure the necessary protection of the field of delivery both during labor itself and during convalescence.

Rupture of the uterus occurs much less frequently now than it did a generation or two ago, when physicians showed an almost inexplicable disinclination to assist nature by instrumental intervention. The dangers incident to a prolonged second stage are now quite thoroughly recognized and it is seldom that a normal uterus ruptures simply as a result of thinning of its walls from too long continued expulsive efforts or from pressure necrosis. Most frequently rupture occurs either from the presence of a fibroid which has produced pathological thinning, or from efforts at turning made with too great vigor or too long after the rupture of the membranes. The prudent obstetrician recognizes the fact that in certain conditions of the uterus, when the contractions are unusually violent or persistent, the introduction of the hand and the manipulations necessary to turning are fraught with the utmost danger, and the dangers under such circumstances may be much greater even than those of a Cesarean section.

Lacerations of the cervix, vagina and perineum may be considered together, and here I think the present generation is guilty of sins of commission vastly more than our predecessors were guilty of sins of omission. It is confessedly impossible in all cases to prevent these lacerations, but in a large proportion of cases, altogether too large a proportion, these lacerations are the direct result of the too hasty or injudicious use of the forceps. I say this advisedly and as a result of several years of careful investigation of hundreds of cases that have come to me for treatment for conditions the direct result of these injuries.

A normal labor may be defined as one that terminates within twenty-four hours from its beginning, and without injury to mother or child. Of this twenty-four hours all but one or two hours will be taken up with the first stage. Much more than this time may be consumed in the first stage without harm to either mother or child. If the first pains are not too frequent or too severe, a first stage may, without being pathological, last for even two or three days with no effect whatever upon the child, and with no ill-effect upon the mother. An ordinary second stage, however, will not exceed two or three hours, although many times even a longer second stage, if the pains are not particularly frequent or strong, is perfectly normal.

A normal labor should not be interfered with, and any interference, manual or instrumental, is fraught with more or less danger to mother or child, or both. I make this statement deliberately and advisedly. Our predecessors were too timid, and as a result of this timidity, to use no harsher term, many lives were sacrificed, great and unnecessary suffering was endured, and infinite morbidity ensued. But too many physicians of the present day have gone to the opposite extreme, so that their sins are those of commission. The too early and too frequent resort to instrumental delivery is responsible for many serious results. A dead baby with a crushed or disfigured head; a ruptured cervix, vagina and per-

ineum; a collapsed and moribund mother, with a history of forceps delivery undertaken 12, 10, or perhaps only 6 hours from the onset of a first labor, is a picture which is to be seen too often in the experience of a consulting surgeon. The scene does not always close with the lethal exit of the mother, or even of the child, but there follows a tedious convalescence after an immediate operation on the lacerated perineum, with a later operation for the repair of the torn cervix. That is all, provided the patient escape the removal of appendages, made necessary by resulting infection.

A year ago an enthusiastic young gentleman presented to this Society a paper pleading for the earlier use of the obstetric forceps. It is most significant, not to say amusing, that this year the same gentleman is announced for a paper on "The Repair of the Perineum."

It should be impressed most vigorously and pertinaciously that labor is a physiological process and that under all ordinary circumstances delivery will be naturally and safely accomplished. If a physician has not time to do obstetrical work he may refuse engagements or decline the call when it comes, but if he has once accepted the case he is bound professionally, morally and legally to give to the woman and her unborn child all the time that may be necessary for her safe delivery, and no honorable and conscientious physician will do otherwise.

#### OBSTETRIC FEES TOO SMALL.

I know that in many parts of the country, indeed in most, the fees which physicians receive for obstetric work are ridiculously inadequate. There is no comparison between these fees and the fees received for the ordinary routine work of the profession, and yet the lives and well-being of two individuals, and the happiness of many others, are at stake in every labor, and the responsibility of the physician is correspondingly great. I doubt, however, if the ordinary physician in the state of Ohio receives on an average \$10 per case for his obstetric work, this fee including not only his attention during the progress of the case itself, but by custom one to three subsequent visits. I know of nothing in our profession in which reform is more needed than in this particular. An obstetric engagement, carrying with it the responsibility which it does, should certainly furnish as much compensation as a mere broken leg. It is true, perhaps, that among the poorer classes no larger fee can be paid, but the principle should be so far established and the fee-bill so changed that, as in other surgical work, the fees of the rich should make up for the lack among the poor, while for the poorest classes in general clean, skilled midwives could advantageously take the place of physicians for ordinary attendance, the physician being sent for merely in cases requiring intervention or the repair of lacerations.

#### MISUSE OF INSTRUMENTS.

Instruments should be used only in the interests of the mother or the child, and never simply to save time or suit the convenience of the physician. Convulsions, threatening the life of the mother, or labor so prolonged as to threaten the integrity of the uterus, exhaust the mother or destroy the child, undoubtedly demand instrumental intervention even at the risk of laceration of cervix and perineum. These can be repaired, but the life of the child or the mother can not be restored. With the soft parts dilated or dilatable, but with such a disproportion between the passage and the passenger as will result merely in a long and exhausting, even if not dan-

gerous, second stage, the forceps should be used; but the attendant should be fully satisfied that the soft parts are in suitable condition, since otherwise even if the superficial parts remain intact the underlying fascia may be lacerated with resulting loss of support to the pelvic organs.

But this has not been the teaching, I am afraid, of modern obstetricians, at least if the teaching can be determined by the practice of those who have been taught. I think it is the experience of every man having a large consultation obstetric practice, to be called repeatedly to cases by the physician, who expects him to at once deliver with forceps, and to find the patient in good condition, the membranes unruptured, the cervix half or two-thirds dilated, the vagina only partially relaxed, the perineum not yet reached by the descending head and its tissue far from ready for delivery; the patient a primipara in whom labor had commenced six to twelve hours before. Were convulsions present he would unquestionably apply the forceps and deliver with perhaps a saving of the child and rupture of cervix and perineum. He knows that the woman will deliver herself, if given a reasonable length of time, safely, satisfactorily and without intervention. He explains the matter to the attending physician and sees the case with him three or four hours later. Finds labor progressing and again postpones intervention until finally the patient delivers herself. The attending physician, if wise, has probably been taught his most valuable lesson in obstetrics, the lesson of judicious waiting.

But this is evidently not the teaching which too many young men receive before their graduation, or perhaps after it. In the *Philadelphia Medical Journal*, of April 13, page 706, in this, the first year of the twentieth century, is an article by a well-known teacher of obstetrics in a New York post-graduate school, in the course of which the writer, in alluding to a series of his cases, states that these cases were nearly all of them "operative ones or were made so because of the presence of an ever-inquiring audience. All my cases were delivered before an audience of physicians who . . . were unwilling to camp over night in a pauper hospital to watch a tedious labor case. . . . Most of the cases would have delivered themselves normally."

Here now is a teacher who reports his work without apparently a suspicion of impropriety. He has performed these operations before a class of physicians who, impressed with the utter indifference with which he interferes with what he confesses is normal labor simply to demonstrate to them methods of procedure, will return to their own homes prepared to carry out in their private practice that which they have thus seen demonstrated in a public clinic. Such practice and such teaching are wholly bad and utterly indefensible. If the antivivisectionists should get hold of that teacher and his work I think before they got through with him he would have learned that there is a God in Israel.

Meddlesome midwifery is bad. This is a statement as old as intelligent obstetrics, but the misuse of this aphorism has done much mischief, since timidity born of ignorance does not properly weigh the meaning of the word meddlesome. Meddlesome midwifery is not that which intervenes in abnormal or pathological conditions, but it is that which interferes officiously with normal processes. In conclusion, then, the prevention of pelvic diseases during and after labor consists, in a word, in cleanliness, patience and intelligent intervention.

## PREVENTION OF PELVIC INFLAMMATORY DISEASES AFTER MARRIAGE.\*

RUFUS B. HALL, A.M., M.D.

PROFESSOR OF GYNECOLOGY, MIAMI MEDICAL COLLEGE.  
CINCINNATI, OHIO.

Our present knowledge does not extend far enough to enable us to have any influence in preventing benign and malignant growths of the female pelvic organs. For this reason they will be wholly disregarded in this discussion. I have, therefore, somewhat modified the title of my paper as published in the program and will limit my remarks to the prevention of inflammatory pelvic diseases after marriage, as they are preventable in a large majority of instances.

It has been said that statistics are worthless, but I am convinced that carefully tabulated records of cases coming under the observation of physicians are very valuable, especially when honestly used in a discussion like this one. The following statistics have been taken from my private office records, where every case that enters my consultation-room is carefully recorded. These results may be of interest and value to us in this discussion. The records show that in 498 cases of inflammatory disease of the uterine appendages, or of inflammation in the pelvis, or both, including those having one or many attacks, the infection was due to the following causes: Gonorrheal infection that could be distinctly traced, 247 cases. Of this number 101 required an abdominal section for relief, and of this number a large majority were pus cases. The remaining gonorrheal cases, 146, were not advised to have a section made. Their disease was not serious enough when I saw them to justify a section for the removal of the appendages, and other means were instituted for the relief of their symptoms. How many of this number subsequently came to the operating table the writer is unable to say, but he is reasonably certain that a number of them would eventually be compelled to have a section made for relief. In 143 cases the cause of the inflammation was either an abortion that was unavoidable or induced. A very large percentage of the cases were induced abortion, usually done by the patient herself. Of this number 29 had to be subjected to a section for relief and 114 were otherwise treated, most of them making symptomatic recoveries. I wish it distinctly understood, in passing, that these cases, both gonorrheal and septic, were almost all of them of long standing, from a few months to a number of years, before consulting the writer. Especially is this true in reference to the cases which were subjected to an abdominal section where the cause of the disease was an abortion. In 52 cases the cause of the inflammation was due to the laceration of the cervix and perineum, with malposition of the uterus. Of this number 18 cases were subjected to a section. The remaining number were otherwise treated. Exposure during the menstrual period, or "taking cold" at that time, was recorded as the cause in 29 cases. In the majority of these cases the patients were unmarried, and there is reason to believe that some other cause might be assigned. In 9 of these cases it was necessary to make a section for their relief and 20 did not require a section. Tubercular peritonitis was the cause in 27 cases. Of this number 20 cases were subjected to an abdominal section and 7 were not so advised, because the latter number had no accumulation of fluid or pus that could be diagnosticated.

\* Read in a Symposium on the Prevention of Pelvic Disease, before the Ohio State Medical Society, at Cincinnati, May 9, 1901.

Thus it is seen that the two chief causes of pelvic inflammatory diseases are gonorrhea and septic infection following abortion. The prevention of the former has been discussed by the writer on previous occasions, and for this reason will not be considered in all of its phases at this time more than to remind you of the duty you owe to the laity of imparting knowledge upon every possible occasion upon the subject of gonorrheal infection. The physician should instruct young men of the danger to the health of their future wives should they contract gonorrhea. In treating the disease in the male the physician should be certain that the patient has remained well for a period of many months before permitting him to marry. It is a lamentable fact that a very large percentage of the cases referred to in this paper were the wives of men who had the disease before marriage and believed themselves cured; but they infected their wives, in not a few instances, many months after marriage. The writer is still of the opinion expressed in his paper previously published<sup>1</sup> that we must look to the education of the laity for the prevention of gonorrheal infection. Further experience has only emphasized the lesson there taught: "I would advise that during the last year in high school, in every school in this land, a text-book be employed embracing embryology, hygiene, anatomy, and physiology including sexual physiology, and that these subjects be taught to every student, both male and female. This could be accomplished without shocking the morals of the most susceptible or fastidious individual by dividing the classes so as to separate the sexes. A female teacher should teach the girls, and a male teacher the boys."

I can not dismiss the subject without reminding you of the fact that gonorrhea, unrecognized as such, is the direct cause of a long list of what might be termed minor ailments of the female, viz., subacute and chronic inflammatory diseases of Skene's glands and of the glands of Bartholini, which not infrequently result in abscesses. Another complication is inflammation of the urethra, often extending into the bladder and causing cystitis, which is most difficult to cure and in not a few instances remains uncured. The glands of the mucosa also become involved, resulting in cervical and corporal endometritis, with a discharge of the most persistent character. This condition frequently causes sterility or produces a congested condition of the uterus, with dragging sensation in the abdomen, with neuralgia and most serious reflex nervous disturbances. In addition to the above-named ailments we often see the infection extend from the uterus into the tubes, producing salpingitis, ovaritis and attacks of pelvic peritonitis, leading to graver forms of pelvic disease. If we could eliminate gonorrheal infection the gynecologist would lose no small percentage of the patients who come to his consultation-room. The number of operative cases for the removal of pus would be greatly lessened, and we would prevent much of the suffering of womankind.

Septic infection following abortion from retained membranes is of frequent occurrence, and in those cases where the patient makes a primary recovery, as they usually do, there is left an endometritis which is difficult to cure and often leads to salpingitis. The subject of induced abortion is one that is constantly brought before the physician in some of its phases. Seldom a month goes by that some married woman does not come to her physician and state that she is pregnant and wishes to know what she can do to interrupt it. She will fre-

quently tell you that she has taken medicines of various kinds to bring on her menses, but they failed to do it. When we look over our records we find a large number of women suffering from uterine disease which was caused by an induced abortion, and many of the most serious cases calling for the gravest surgical operations belong to this class. Too much stress can not be laid on the gravity of the procedure, and furthermore, it must always be borne in mind that death may be the immediate result of an abortion. Especially is this so where women try to produce abortion upon themselves. About a year ago I saw three cases within three weeks in consultation with other physicians in this city where the women had either produced or attempted to produce abortions upon themselves. In each instance the patient was a married woman, mother of one or more children, and the only reason she had for producing an abortion was the desire not to raise another baby. In each instance the patient was suffering from septic infection. There was a large accumulation of pus in the pelvis, in two of the cases, with profound sepsis. These patients were subjected to vaginal section with the removal of a large quantity of foul-smelling pus. One patient died within a day or two after the pus was evacuated, from her pre-existing sepsis, which had existed for seven or eight weeks. The other patient had a long, tedious convalescence, is a semi-invalid now with adherent tubes and ovaries, and with no immediate prospect of recovery. The third patient referred to had profound sepsis with no accumulation of pus that could be determined. She died within a few hours of my first visit, without any operative interference. These are only a few cases that could be narrated of a long list that every physician is too familiar with. If the patient does not die immediately following the abortion, as stated before, it may be followed by such a serious pathological lesion in the pelvis as to call for the most heroic surgery. They realize their mistake when it is too late to be of service to them and would change it all if they could.

These cases are a fair illustration of what operators see from this cause very frequently. I am inclined to believe that many women are ignorant of the dangers they incur from an induced abortion until it is too late. I make a plea for the more extensive dissemination of knowledge by the family physician to his patrons upon this important subject. Few women would produce an abortion upon themselves or consent to have it done, unless they had a crime to conceal, if they knew of the dangers attending it as the physicians know them. It is in these cases that it is the physician's duty to impart the knowledge. He should explain to her the danger of retained membranes during the early months of gestation and the great danger of septic infection on account of the retained membranes. He should tell her that if she has sepsis afterwards and recovers from it she is left with a septic endometritis which may lead to a salpingitis with suppuration in one or both tubes, necessitating a section for their removal before she is relieved of her pain. It is in this class of cases that an ounce of prevention is worth a pound of cure. They are all preventable; indeed, their occurrence ought to be comparatively rare. It is for this reason that the profession should be united in the effort for the prevention of these diseases.

It is evident that if we are to prevent pelvic inflammation following abortion it is necessary to prevent septic endometritis. This could be done in all instances if the physician could see the patient early enough to thoroughly empty the uterus before decomposition of

1. *American Journal of Obstetrics*, 1890.

the membranes takes place, but unfortunately, he sees these cases only after this has been in existence for many days, and often he sees them for the first time when they are thoroughly septic from this cause.

By referring to the statistics it will be observed that laceration of the cervix and perineum play no insignificant rôle in the cause of pelvic inflammation. In laceration of the cervix, with the usual laceration of the perineum and the retroversion that so often accompanies these injuries, with the endometritis following it if the injuries are not repaired, we have a condition present which may lead to pelvic disease in a large percentage of these cases. These patients all have subinvolution following their delivery and many of them drift along until the endometritis becomes chronic or even a salpingitis is established. It is the physician's duty to repair the cervix and perineum within a few months after injury, before there is a chronic endometritis and salpingitis established and before the uterus has been in the malposition long enough to cause extensive disease of the ovaries from pressure, to which the ovaries are always subjected after they are dragged down with the uterus in its abnormal position. If the cervix and perineum are repaired within a few months after delivery in all cases where the uterus is retroverted, and that organ temporarily supported by a properly fitting pessary, the physician would save his patient great suffering and prolonged invalidism. It is the physician's duty, where he has waited on a woman in confinement, to examine her carefully within four months after her delivery and make careful notes as to the injuries and the position of the uterus and ovaries at that time; and where the cervix is injured, even if it be slight, and there remains subinvolution, he should curette the uterus and repair the cervix as a means of prophylaxis.

Many of these patients do not complain even where there are extensive tears of the cervix and perineum until several months after delivery, when endometritis is well marked and unmistakable signs of salpingitis are present. The extension of inflammation through the tubes in long standing endometritis following injury of the cervix is a condition not infrequently met with. It is a well-known fact that subinvolution of the uterus, which may continue for many months, is the rule after extensive laceration of the cervix. It is in this class of cases that we occasionally see a chronic catarrhal condition continue for an indefinite period, with depreciated general health of the patient and changed type of menstruation, the patient complaining of pain in the back and abdomen. These symptoms extend over a period of many months until finally the patient goes to bed with a sharp attack of pelvic inflammation. Upon thorough physical examination the physician finds that salpingitis already exists. It may be too late now to cure this patient and prevent recurrent attacks of pelvic inflammation, but I have every reason to believe that if the injury to the uterus had been repaired and the retroversion corrected within a few months after her delivery she would have been perfectly and permanently cured and thus prevented a life of invalidism. Just as long as women bear children just that long will these injuries to the cervix and perineum be recorded against the obstetrician. That should be no cause for chagrin on his part, but neglect to repair them and prevent preventable diseases should be an opprobrium to the medical profession.

The greater frequency of peritoneal tuberculosis in the female as compared with the same disease in the

male is a well-recognized fact, and it is fair to presume that the bacillus enters the peritoneal cavity through the uterus and tubes. This theory is sustained by the clinical facts gained in the operating-room in dealing with this disease. If in the future it is definitely settled that the route of infection is through the vagina the question of prevention will be an interesting problem. The fact that the disease occurs in the virgin as well as the woman who has borne children only emphasizes the necessity for careful investigation to settle definitely the mode of infection in this dread disease.

Guarding against the above-named sources of infection is not the only branch of prophylaxis that the intelligent physician is called upon to consider. It is not at all uncommon for the physician to be consulted by one who has recently married in regard to the "best method of preventing conception." The statement is made in almost every instance that they do not wish to have children for a few years, but would not object to one or two after a while. They do not realize the danger that the wife incurs of laying the foundation for a chronic disease which may leave her forever sterile and possibly an invalid as well. The various methods and practices used to prevent conception have a distinct bearing in establishing certain pathologic pelvic conditions in not a few women, especially the practice of using cold water as a vaginal douche. This practice not infrequently causes endometritis which goes on to salpingitis regardless of the best directed treatment for relief, until finally the patient is a subject of pelvic inflammation, with possibly suppuration of the tube, which necessitates a section and removal of the diseased organs for relief.

In closing my remarks I wish once more to emphasize the statement that prevention of pelvic inflammation in women must come largely through the enlightenment of the laity by the medical profession. This can be done only through the profession, and I am convinced that in time it will be done and these preventable diseases will be greatly lessened.

#### THE PREVENTION OF PELVIC DISEASE BEFORE AND DURING PUBERTY.\*

W. H. HUMISTON, M.D.

Associate Professor of Gynecology in the Medical Department of Western Reserve University; Gynecologist-in-Chief to St. Vincent's Charity Hospital.  
CLEVELAND, OHIO.

So intimate is the association between the normal functional life and soundness of mind and body in the young woman, that my part of this discussion resolves itself largely into the subject of general hygiene. However interesting the résumé of authorities upon proper diet, dress, posture and exercise (both mental and physical) might prove, yet I shall consider but a few points of more specific character.

The first question which one naturally asks is: "What are the pathologic conditions of the uterus and its adnexa whose causative factors may be traced to the period leading up to and beyond puberty?" 1, retroversions and retroflexions of the uterus; 2, endometritis; 3, metritis; 4, sclerotic and cystic degeneration of the ovaries.

1. *Displacements.*—Goodell has related a number of cases of sudden displacements of the uterus caused by the making of a misstep, or by jumping from the high old-fashioned stage coaches when the bladder had become, during a long journey, greatly over-distended.

\* Read in a Symposium on the Prevention of Pelvic Disease, before the Ohio State Medical Society, at Cincinnati, May 9, 1901.

Many children are loath to give up a moment of their time at play to answer the call of nature, and the older ones are often compelled by their modesty or by unfortunate circumstances to withhold from urination beyond the measure either of comfort or safety. I see in this one of the most frequent causes of the backward displacement.

The habit of undue bending over of the body while sitting, together with the wearing of corsets, which modifies the direction of the intra-abdominal pressure, is another evil universally recognized.

2. *Endometritis*.—The mucous membrane lining the cavity of the uterus is just as liable to catarrhal processes as are like membranes elsewhere in the body, and more susceptible in fact because of the recurring hyperemia attending the menstrual flow. Acute suppression of the menses caused by sudden chilling of the body after prolonged exertion—as one so frequently sees the dancer in the interim between waltzes rushing to an open window for a breath of air—is a direct factor in the causation of an acute endometritis. "I caught cold while menstruating" is the too common phrase to which we have to listen.

This leads to the more chronic forms of endometritis—hypertrophic and hyperplastic glandular endometritis—which I more commonly meet in the virgin.

3. *Metritis*.—This in the young unmarried woman is fortunately less common, but there is a condition described by Mary Putnam Jacobi, and termed by her menstrual subinvolution, which leads to the same pathologic change as does subinvolution following parturition. This condition is seen as a sequence of endometritis in malpositions of the uterus, and is of such serious character that early interference is absolutely necessary to preserve the function.

4. *Ovarian Sclerosis*.—In the non-inflammatory, or as I would choose to term it, primary sclerosis of the ovary, there must be some active etiologic factor of which we as yet know nothing. I hesitate to believe with Osler that the fault lay in the material of which the parts are builded—an inheritance—but that the cause lay rather in some fault of nutrition in the child. It does, however, occur as a sequence to changes in the uterine structure.

#### PREVENTION.

This brings me to the discussion of the prevention of these disorders. There is no new thought which I can bring to bear to lighten the burden of the young woman.

I can only give added evidence of the necessity of wisely guiding her to a practical knowledge of the conditions which obtain through her often-repeated functioning cycles.

We must find fault with our civilization when we learn of the care which primitive peoples were wont to exercise over the young girl and the woman. It would seem that what they did from purely a religious duty we might be wise enough to attempt at least to carry out for the benefit of our state. It is said that among some of these early peoples it was a time of greatest moment when the young girl approached her first menstrual period, and most carefully was she protected and guided. They had especially designed huts where they were obliged to remain during each period in enforced idleness—not even being allowed to stand erect—their huts being too low to permit it. The Mosaic law compelled such an enforced retirement.

What a contrast to the almost total disregard which we to-day practice toward our children! Engelmann<sup>1</sup> says that "functional disturbances are least in the first years of pubertal development in the high school, increasing with each year, increasing in the normal school and college, increasing with intensity and seriousness of work." He refers to the New England woman as "supposedly more perfect than in any other section, intellectually above the average, but with a physique below par, with greatly reduced reproductive powers—all due to the forcing of study at the age of development."

Dress reform is spreading widely and rapidly; more attention is being given to the proper diet of the young; physical training forms a part of the curriculum of the public and private schools, but there is a tremendous waste of vital energy in the ever-increasing force toward mental acquirements—energy necessary to proper physical development, energy-requisite for normal functional life.

"An ounce of mother is worth a pound of doctor," but the burden of responsibility should rightly rest upon the physician, whose care it should be that the mother understand the requirements of the developing girl, and appreciate the necessity of proper methods for equably distributing, during the years of growth and early maturity, the force which will round out her mental, physical and functional qualities.

#### ISOLATION OF BACILLUS TYPHOSUS FROM UNUSUAL LOCALIZATIONS—CHOLECYSTITIS, MENINGITIS AND A FIVE MONTHS' FETUS.\*

O. McDANIEL, M.D.

Assistant Bacteriologist, Bacteriological Laboratory of the Minnesota State Board of Health.

MINNEAPOLIS, MINN.

The first case to be reported is that of the isolation of *B. typhosus* from a case of cholecystitis.

The patient, a physician, at the time of the attack was in attendance upon typhoid patients in a mild epidemic which occurred during the fall of 1900 in a mining district in the northern part of the state.

Through the kindness of Dr. R. E. Cutts, Minneapolis, it is possible to give the following notes from the history:

CASE 1.—Dr. G. A. C., male, aged 24. Family history is negative; there was no history of previous typhoid infection. Present illness began Sept. 30, 1900, with malaise and evening temperature of 100 F. On the second day the patient attended to his work but had some fever and pain in pit of stomach; no pain or tenderness of bowels. Symptoms continued, the evening temperature reaching 103 on the third day. Patient, however, continued his work until the fifth day, when he came to Minneapolis by rail, a distance of 300 miles, and was at once admitted to St. Barnabas Hospital. Specimen of blood taken on this day gave a positive Widal reaction, dilution 1:25.\*\*

Next morning—the sixth day—patient was examined by Dr. J. W. Bell, and presented the following condition: Tongue was coated with a white fur, but not dry. There was marked pain and tenderness in the region of the stomach. Pain was constant, of a gnawing character, and was aggravated by the taking of liquids. During deglutition the pain was most marked about the cardiac orifice. No tenderness of bowels, no distension. Slight constipation, but otherwise stools normal. There

\*\* The method used in this laboratory is that described by Westbrook and Wilson, "The Serum Diagnosis of Typhoid Fever." Philadelphia Medical Journal, March 26, 1898.

was slight hacking cough, but no other evidence of pulmonary disturbance. Evening temperature 102.4, pulse 98.

On the seventh and eighth days condition remained much the same, the temperature ranging from 99.4 to 102.4. During the afternoon of the ninth day pain became more severe, and was most marked in the right hypochondriac region, necessitating the use of morphin. The pain gradually increased in severity, becoming localized in the region of the gall-bladder and intermittent in character.

During the night of the eleventh day the pain was so severe that one grain of morphin in three doses was given hypodermically with but moderate relief. On the morning of the twelfth day a distinct tumor apparently 4 to 5 inches in diameter was felt just below the liver. Blood count (Dr. G. D. Head) at this time showed 18,500 leucocytes. A diagnosis of cholecystitis with abscess formation was made by Drs. J. E. Moore and J. W. Bell and operation advised. An afternoon leucocyte count showed a decrease to 17,000 leucocytes.

On the thirteenth day the tumor was considerably reduced in size, the patient felt much better and operation was deferred. The improvement was but temporary; the intermittent pain continued with increasing tenderness in right hypochondriac region.

On the seventeenth day cholecystotomy was performed by Dr. J. E. Moore. The gall-bladder was found distended with a bile-stained mucoid fluid, that in the most dependent portion being slightly turbid. No calculi were found. There was a small amount of serous fluid posterior to the gall-bladder with a few very recent adhesions. Palpation of appendix and other abdominal organs was negative. Permanent drainage was established and the patient made a good recovery.

Cultures made from a portion of the fluid which was aspirated before incision into the gall-bladder showed an unmixed growth of an actively motile bacillus—*B. typhosus*—with the following characteristics:

Broth: Cloudy; no pellicle.

Dunham's peptone solution: Cloudy, no pellicle, indol reaction absent.

Capaldi-Proskauer solution: Red, at the end of 24 hours and remained red.

Litmus milk: Blue tint slightly lessened—no coagulation.

Dextrose agar shake: Small round colonies throughout—no gas.

Agar slant: Small, round, slightly raised, whitish colonies.

Litmus dextrose agar slant (M. S. F.†): Medium turned red at end of 24 hours; remained red.

Litmus lactose agar slant (M. S. F.†): Medium unchanged at end of 24 hours. After two weeks still unchanged.

Litmus saccharose agar slant (M. S. F.†): Medium unchanged at end of 24 hours. After two weeks still unchanged.

Litmus maltose agar slant (M. S. F.†): Medium turned red at end of 48 hours. (Slower than dextrose.)

Potato: Growth invisible except for moist appearance.

Reaction with blood of known typhoid patients was positive in every case in a dilution of 1 to 25 and also 1 to 100. A similar reaction with patient's blood was also present.

Pathogenesis: Intraperitoneal inoculation of 1 c.c. of a 24-hour broth culture killed guinea-pigs in less than 24 hours. At autopsy they showed marked peritonitis.

Within the past five years the literature of cholecystitis complicating and following typhoid fever has been carefully presented by several writers and Camac<sup>1</sup> in 1899 collected forty-three cases, in thirty-four of which *B. typhosus* was isolated. Since this publication a number of other cases have been recorded.

A study of the reported cases shows that symptoms of cholecystitis arising during the course of typhoid fever rarely occur as early as the tenth day, but most commonly between the twentieth and thirtieth days. Guar-

nieri<sup>2</sup> in 1892 reported a case of primary typhoid cholecystitis without intestinal lesions, which was verified by autopsy. Cushing,<sup>3</sup> Pratt<sup>4</sup> and others have since reported cases in which there seemed to be no lesions of the intestines.

In the case here reported the symptoms of gall-bladder involvement were marked early in the course of the illness. This fact, together with the absence of definite symptoms of intestinal typhoid including an atypical temperature curve, suggests the possibility of its being a case of primary cholecystitis unaccompanied by intestinal lesions.

The increased leucocyte count may have been due to the slight local peritonitis† which was present or to several small furuncles which appeared below the knee, one of which was opened three days after operation and yielded a pure culture of *S. pyogenes aureus*.

Hunner<sup>5</sup> has reported a case of typhoid cholecystitis occurring eighteen years after an attack of typhoid fever in which the leucocyte count was as high as 29,000. The anatomical findings in this case were parallel with those herein reported. These cases would seem to indicate the necessity for fuller observations concerning the leucocyte count in typhoid cholecystitis.

CASE 2.—The second case is that of the isolation of *B. typhosus* from a patient who developed meningitis following typhoid fever. The case occurred in the practice of Dr. F. R. Woodward, at Asbury Hospital.

Mr. N., a private in the 15th Minn., U. S. V., was taken sick during the epidemic of typhoid fever which occurred in the fall of 1898 at Camp Ramsey.

The patient had a mild run of typhoid fever in which the temperature but once reached as high as 102 F. The Widal reaction was present. The patient was discharged on the 38th day of the disease, the temperature having been normal from the 17th day except for a slight rise on the 23d day, which followed 12 hours after repeated doses of magnesium sulphate.

In the afternoon of the day in which he was discharged the patient returned to the hospital somewhat under the influence of liquor. (No particulars in regard to the patient's condition at this time could be obtained as the hospital records of this second illness together with the notes and autopsy record prepared by Dr. C. B. Lenont were lost.) Fever was present and symptoms of meningitis developed, the patient dying five days later.

Autopsy showed an extensive purulent inflammation of the cerebral meninges. Dr. H. E. Cotton collected in a sterile bulb purulent fluid from the base of the brain. Direct coverslip preparations from this fluid showed numerous small bacilli, some of which were within the polymorphonuclear cells. Cultures showed the only organism present to be a bacillus with all the characteristics of *B. typhosus*. This was, so far as can be determined, a meningitis due to unmixed infection with *B. typhosus*.

CASE 3.—Through the kindness and interest of Dr. Thomas S. Roberts, of Minneapolis, the opportunity and materials for examination were afforded in the third case which, as noted in

2. Contributio alla patogenise delli infezione billari. Rivista generale italiana di clinica medica, 1897. Ref. Baumgarten's Jahresbericht, 1897, p. 234.

3. Johns Hopkins Bulletin, May, 1898.

4. Jour. of Boston Soc. of Med. Sciences, April 23, 1901.

† It may be noted that an abundant growth of *B. typhosus* together with two or three colonies of a white coccus were obtained from a gauze sponge which was packed around the gall-bladder during aspiration, and the placing of stitches. Unfortunately a culture from the region surrounding the gall-bladder was not taken until this chance for infection from the gall-bladder contents had occurred. Presumably the typhoid organisms escaped from the gall-bladder during aspiration, and the few white staphylococci came from the deeper layers of the epidermis.

5. Johns Hopkins Hospital Bulletin, August-September, 1899.

† M. S. F.—Agar rendered primarily muscle sugar free by inoculation with *B. Coll communis* as recommended by Theobald Smith.

1. Am. Jour. of Med. Sciences, March, 1899.

the abstract, was that of the isolation of *B. typhosus* (?) from a five months' fetus.

Without apparent cause, the mother aborted one week after the beginning of convalescence from typhoid fever. The course of the fever had been typical and the Widal reaction was present in her blood as well as in that of the fetus.

No gross lesions were discovered in the fetus, but from its organs, peritoneal fluid and heart's blood, cultures were made immediately on receipt in the laboratory, i. e., 36 hours after delivery of the mother. It had been kept on ice in the interim.

From the spleen, liver and peritoneal fluid was isolated an organism which presented all the characteristics of *B. typhosus* with the one exception that it formed gas in the media containing dextrose. In the media which contained lactose, maltose or saccharose, in milk and other cultures and in every other respect it was indistinguishable from parallel cultures of *B. typhosus*.

It was actively pathogenic for guinea-pigs, in whom a fatal peritonitis occurred in less than twenty-four hours after intraperitoneal injection of 1 c.c. of fresh broth cultures, and from whose organs it was again recovered. Blood of known typhoid patients in a dilution of 1 to 25 reacted to this bacillus, though in about half of the cases the reaction was not quite so marked as with *B. typhosus*. This is, however, common in freshly isolated cultures of *B. typhosus*. It should be noted also that the blood of both mother and fetus reacted to this bacillus.

In addition to this micro-organism obtained from the spleen, liver and peritoneal fluid of the fetus there were isolated from both the spleen and liver two other organisms. One resembled *B. typhosus* in most respects, but did not acidify maltose, was feebly if at all motile and grew less abundantly than parallel cultures of *B. typhosus*.

The third micro-organism was non-motile and did not ferment any of the four sugars tested. It was found in the heart's blood also. From both peritoneal fluid and liver a fourth organism was obtained. It coagulated milk, acidified all of the four sugars without the formation of gas, but was, however, very short and somewhat resembled a diplococcus.

Further study of these four micro-organisms will be necessary before making a full report of the case. Identification of the three last mentioned has not been completed, though they are still under observation.

In consideration of all of its characteristics, can the first bacillus be considered as *B. typhosus*, which has undergone some modification in the fetus whereby ability to produce gas—in addition to acid—from dextrose was acquired?

It has been shown by Peckham<sup>6</sup> that *B. typhosus* may be led to produce indol by change in environment. Is the production of gas by a bacillus a greater departure from the recognized limits than the production of indol? Before answering this question finally it will be necessary to study more thoroughly the influence of fetal tissues, glycogen, etc., upon *B. typhosus*. The mechanism of the production of the positive Widal reaction in the blood of the fetus is explained in this case if it be possible to consider this bacillus an aberrant type of *B. typhosus*.<sup>7</sup>

*B. typhosus* has been reported present in the fetus by several observers who made no mention of a corresponding Widal reaction. Whether this was undetermined or absent was not stated. The presence of the blood reaction in the fetus has not been demonstrated in cases in which infection with *B. typhosus* could be absolutely excluded.

#### DISCUSSION.

DR. MAXIMILIAN HERZOG, Chicago—I have seen a few cases of peculiar localization of the typhoid bacilli, or peculiar complications brought about by it. A case of interest occurred in the practice of Dr. Maywit, Chicago. The case had been diagnosed at a certain stage as typhoid fever, and confirmed by a Widal test. The patient acting peculiarly, a probable diagnosis of tubal pregnancy complicating typhoid was made. An operation performed by Dr. F. Henrotin demonstrated the correctness of the diagnosis; a 4-week embryo and a ruptured tube were found. A long suppuration followed the operation and the pus examined showed the presence of bacilli identical in their morphology with typhoid bacilli. Pure cultures, unfortunately, were not made, but there is hardly any doubt that the long-standing suppuration was caused by the typhoid bacillus. I recently saw another unusual localization of the typhoid bacillus; the case occurred in the practice of Dr. Chew of Chicago. The patient, a young man 28 years old, had a typical typhoid fever, which ran its course. In the period of convalescence, a temperature again developed, and the objective symptoms of pleurisy became manifest. The pleural cavity was tapped, and some pus was obtained. This pus contained micro-organisms resembling typhoid bacilli. A subsequent careful examination of those bacilli by the usual culture method demonstrated them to be typhoid bacilli. The pleurisy took a somewhat protracted course, but the patient eventually recovered.

DR. F. F. WESBROOK, Minneapolis—In the first case reported by Dr. McDaniel we are led to ask, was this not perhaps an abnormal case of typhoid fever? Was there not something in addition to the cholecystitis such as some lesion of the intestine? I do not think this was excluded, although there was not very much after the operation to call attention to the intestinal tract below where the contents of the gall-bladder entered. I believe at that time the only thing to which special attention was directed was the immediate locality of the operation. Dr. McDaniel's second case was undoubtedly meningitis due to *B. typhosus*. In the last case to which Dr. McDaniel called attention, that of the 5-month fetus, one of the micro-organisms isolated showed the characteristics of bacillus typhosus in every respect but one, namely, the formation of gas. It undoubtedly was a pure culture. One is led to ask in how many respects must a bacillus be typical in order to be classed as bacillus typhosus. Is gas formation a fatal objection to such classification? This bacillus was typical in every other respect culturally, and in all points morphologically characteristic. It was pathogenic for guinea-pigs and reacted to the blood of known typhoid patients, while the blood of both mother and fetus reacted to *B. typhosus* and to this bacillus. These characteristics should probably more than offset the aberrant one of gas production, though, as Dr. McDaniel has stated, more work should perhaps be done before drawing final conclusions.

Dr. Herzog's remarks bring to mind a case which I have recently seen in which, some three or four months following typhoid fever, there developed a tumorous mass slightly below the left nipple and a little to the left of the median line. After some weeks an incision was made to the depth of half an inch and a small amount of pus obtained. Cultures of *B. typhosus*, typical in all respects and so far as could be determined, without admixture with any other micro-organisms, were obtained. In this case and in the first two cases reported by Dr. McDaniel, the bacilli were unmixed and were characteristic in all respects. In Dr. McDaniel's third case there was a variety of possibly closely related organisms, none of which was absolutely identical in all respects with *B. typhosus* or *B. coli communis*. It is in such cases that we hesitate and the longer we work

6. Peckham: *Journal of Experimental Medicine*, vol. II, 1897, p. 549.

7. A number of interesting cases have been collected and three reported by Bolton, *Journal of Pathology and Bacteriology*, vol. VII, p. 137, Feb., 1901, bearing on the relation of the Widal reaction to infection of the fetus with *B. typhosus*. It may be noted that in Bolton's third case the organism isolated from the fetal organs formed indol.

with micro-organisms belonging to the typhoid and colon group the more careful we become in saying when and where we have to draw the line.

### COLD WEATHER ACCOUNTABLE FOR TURBIDITY OF THE URINE.

L. NAPOLEON BOSTON, A.M., M.D.

Bacteriologist to the Philadelphia Hospital; Demonstrator-in-Charge of the Clinical Laboratories of the Medico-Chirurgical College.

PHILADELPHIA.

It is common to find a certain percentage of freshly voided urines to present, upon examination, a variable degree of clouding which may have for its cause many different conditions. Among the most striking of these are those dependent upon thermic fluctuations, and in this connection reference shall be made to the changes produced by exposure of the urine to a temperature near the freezing point. With the approach of marked climatic change and a decided fall in the mercury, the number of turbid specimens collected from private practice and dispensary clinics is greatly increased, while specimens collected from hospital patients are seldom influenced by cold. In the urines brought to the laboratory of the Philadelphia, Pennsylvania and Medico-Chirurgical hospitals during the fall and winter months, the writer seldom observed any increase in the number of turbid urines. It was often noticed in specimens brought by patients to the dispensary of the Howard and Medico-Chirurgical hospitals, as well as in those sent to the laboratory by physicians, collected from their private practices. It was further observed that where two specimens, a morning and an evening, were studied, the evening urine would be found turbid, while the morning specimen appeared normal, and when the morning urine was the older of the specimens the reverse was frequently found. It occasionally happened that the patient had inspected the urine before leaving home and noted its clearness, but after carrying the bottle exposed to the cold for a time, it was found turbid on reaching the laboratory. The common cause for this extreme turbidity is the presence, in such specimens, of amorphous urates which on exposure to certain thermic changes are thrown out of solution, the degree of turbidity and consequently the color and consistence of such urine varying in direct proportion to the amount of urates precipitated. The naked eye may detect a slight finely granular clouding of a grayish-white color, which on close inspection is indistinguishable from that occasioned by amorphous phosphates. This precipitate may become sufficiently dense as to present a thick, heavy, pus-like sediment at the bottom of the bottle, which is seen to rise in the form of a thick ropy cloud when agitated. More common is it to find the clouding of a reddish or yellowish tinge, in which case the opacity varies from that scarcely perceptible to that of a thick yellowish-brown or dark-red color with the consistence of syrup. On standing, the lower portion of the urine may be occupied by this sediment, while immediately above it is a narrow zone of either clear, cherry, or wine color, while the remainder of the urine is highly colored. Turbidity directly ascribable to urates is a common finding in the urine of persons suffering from rheumatism, acute bronchitis, tonsillitis and allied febrile conditions, but is by no means rare in the urine of those apparently in perfect health, and during the period of gestation. In nearly 400 specimens where the turbidity was in part or entirely the result of exposure to cold, it was found that the features above

given were present to a variable degree. The specific gravity ranged from 1018 to 1045, while fully two-thirds of this number were between 1023 and 1033. In striking contrast to what is usually expected in turbid urines, these specimens were exceptionally free from albumin; but two of them showed this body (serum albumin) in considerable amounts. In none of the specimens was a positive reaction for sugar obtained. Fehling's and the fermentation tests were employed. On several occasions there were reactions which simulated that of glucose, with Fehling's reagent, but these were not typical and could not be confirmed by the fermentation test.

Turbidity or opalescence, the result of an excess of amorphous urates, disappears upon the application of heat. A test-tube is filled one-third to one-half its depth with the suspected urine, and the upper one-third of

the column of urine is passed over the flame of a Bunsen burner and heated to a temperature nearing that of the boiling point. The clouding due to urates disappears from the portion of the urine to which heat is applied, before the boiling point is reached, while the unheated portion of the column remains unchanged.— See illustration. By the addition of a few drops of acid to such urines we may cause the precipitation of uric acid, commonest in the form of rhombic plates, but this procedure can scarcely be regarded as one of practical value. In the teaching of clinical diagnosis there appears to be but few substances that are met with more frequently than the one here under discussion, and the reaction thus obtained proves a most satisfactory safeguard against confusion. The more common causes of turbidity to be differentiated from that due to urates are those dependent upon phosphates, bile pigments, pus, mucus, serum albumin with red blood

cells and many granular casts, and urines containing an admixture of vaginal secretions. It may be added that none of these substances clear upon the application of heat as herein outlined. In biliary urines it was commonly seen that the upper portion of the column cleared when heat was applied, but the color resulting from the bile pigments remained unchanged. Microscopic study assists in distinguishing, beyond any possibility of a doubt, substances likely to be mistaken for amorphous urates. However, we are forced to resort to chemical measures in differentiating between amorphous urates and amorphous phosphates. Albumoses coagulate at about the temperature at which urates are returned into solution, but it is improbable that it would be capable of conflicting in any way with this reaction.

### ON THE TREATMENT OF OBESITY.\*

HEINRICH STERN, PH.D., M.D.

Professor of Internal Medicine, New York School of Clinical Medicine; Formerly Professor of the Diseases of Metabolism, St. Louis College of Physicians and Surgeons; Consulting Physician, New York Red Cross Hospital; Visiting Physician St. Elizabeth's and Metropolitan Hospitals.  
NEW YORK CITY.

A rational therapy of polysarcia is only possible on the basis of a more precise differentiation between the principal types or degrees of this metabolic anomaly.

A number of authors have attempted to distinguish between the forms of corpulency. The classification of Immermann<sup>1</sup> into the plethoric and the anemic types, partly on account of a certain clinical justification, but mostly on account of its adoption by Oertel,<sup>2</sup> is the best known and enjoys universal acceptance by later writers on the subject. This differentiation, however, is one of degree more than of character, and, in advanced cases of obesity when pronounced degenerative changes have taken place, the one type can not be distinguished from the other.

Guided by the external appearance, Immermann assigns the cases to one of the two categories: 1, to the plethoric group he refers the instances occurring in the robust; 2, to the anemic class, those obese individuals who display a weakened muscular system. In the following I have delineated some characteristics of the two forms—in their extremes:

|                                    | PLETHORIC TYPE.   | ANEMIC TYPE.                    |
|------------------------------------|---|---------------------------------|
| Occurrence:                        | more frequent in males;                                       | more frequent in women.         |
| Corpulency due to:                 | hyperingestion of foods and liquids;                          | deficient oxidation.            |
| Appetite:                          | excessive;  | impaired.                       |
| Appearance:                        | ruddy;  | pale.                           |
| Endurance:                         | little if at all reduced;                                     | excessively diminished.         |
| Body temperature:                  | normal;   | frequently subnormal.           |
| Integument:                        | smooth, greasy;   | rugose.                         |
| Muscular system and adipose:       | firm;   | flaccid.                        |
| Heart:                             | vigorous (bradycardia in advanced stage weak and arrhythmic); | feeble.                         |
| Arterial tension:                  | increased;  | lowered.                        |
| Blood (hemoglobin and corpuscles): | abundant;   | deficient.                      |
| Edema of lower extremities:        | infrequent;   | frequent.                       |
| Urine:                             | abundant;   | diminished.                     |
| Accompanying conditions:           | lithemia, oxaluria;   | dyspnea.                        |
| Tendency to:                       | arterio-sclerosis;  | hypostatic congestion of lungs. |

It is obvious that in their extremes these two clinical pictures exist more infrequently than in their intermediate degrees—conditions of corpulency partly resembling the one, partly the other type. The vast majority of instances of lipomatosis belong neither absolutely to the

“plethoric” nor to the “anemic” form, and therefore do not permit of a definite classification. Inasmuch as a differentiation is often impossible, the value of the Immermann-Oertel classification, for practical and especially therapeutic purposes, is quite limited and besides often problematic.

#### CORPOREAL SPECIFIC GRAVITY AND POLYSARCIA.

Sometime ago I attempted to demonstrate that the volume weight of the animal body discloses, with a high degree of certainty, the physical condition of its structures.<sup>3</sup>

Fat is the only important tissue constituent which possesses a lesser degree of density than water. Adiposis causes a reduction of the specific gravity of the organism, and that, in the same ratio in which the increase of fatty material has taken place. Polysarcia, however, in spite of its name—much flesh—is neither always dependent upon an increase of the corporeal solids nor upon the relation of protoplasm to fat; it is frequently but the consequence or the manifestation of tissue hydration, and of the increased contents of water in the organism. In other words, rotundity of the body may be due to an absolute increase of protoplasm, to one of protoplasm and fat, to an absolute increase of fat alone, or to an increase of the liquid tissue constituents either per se or together with fatty deposits.

The specific gravity of an individual in a given case of polysarcia, is, therefore, dependent upon the following possible factors: 1, protoplasm +, total inorganic solids +; 2, protoplasm +, fat +; 3, protoplasm stationary, fat +; 4, protoplasm —, fat +; 5, protoplasm —, fat +, H<sub>2</sub>O +.

It is not my intention to dwell upon the polysarcia-corporeal density relation at greater length. Some of my pertaining investigations will be published in the course of the year. Those who are interested in the subject, I refer to my article in the *Medical Record* of February 9, 1901. The few facts, however, which I have related in the foregoing make it evident that the Immermann-Oertel differentiation, as a basis for rational treatment, is without any doubt inadequate and superficial.

Classifications according to the increase in absolute weight, into very pronounced, moderate and slight corpulency, may serve a purpose, if denoting the obesity degree of a certain type. In differentiating between certain obesity forms, the degree classifications are illogical, and, to say the least, useless for therapeutic intents.

The determination of the volume weight of an individual would be but rarely practiced and the corporeal specific gravity would hardly ever become a factor in physical diagnosis if, to ascertain these, we were compelled to employ any volumetric device or tedious mathematical calculations. However, the density of the blood may well serve as an indicator of corporeal density. A series of observations on men, conducted by the writer, has pointed out that the volume weight of an individual in the physiologic as well as in the pathologic state, is reflected in the specific gravity of his blood. That is, that a high blood density corresponds with a high body density, and a non-transitory hydremic condition with a low corporeal specific gravity. Congruous density degrees of blood and body, it is true, were rarely found. Again, the deviation between the two specific gravities in every instance was so slight that it seems rather due to shortcomings in the methods utilized in ascertaining the densities of both blood and body, than to an abnormal

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

distribution of the fluid contents in the organism. The difference between the two densities in these observations amounted, on the average, to about six degrees in favor of the corporeal specific gravity. This figure six may be employed as a standard or coefficient, for the estimation of the volume weight of a healthy adult male from his blood density, by adding it to the latter.

Since reading my first article on the subject—October, 1900—I have had occasion to extend my observations upon the relation of total volume weight to blood density in the female organism. The data obtained are almost analogous to those I had found in males, and the same coefficient, six, is, for all practical purposes, sufficiently accurate for the calculation of the approximate volume weight from the blood density, in the normal female individual.

Again, fluctuations in the physical condition of the body are distinctly reflected in the physical condition of the blood. In the abnormal state, the permanent higher and lower degrees of blood concentration also correspond with a higher or lower specific gravity of the total organism. The various forms of polysarcia are no exception to this rule. The coefficient plus six, as I have convinced myself in a number of observations, may be also utilized in computing from the blood density the volume weight of the obese male or female.

*I am in the habit of determining the type of obesity on the basis of the specific gravity of the individual. Accordingly I differentiate between:*

1. Polysarcia concurring with a relatively high degree of corporeal specific gravity—hyperplasmic obesity or lipomatous hyperplasma.
2. Polysarcia associated with a normal or slightly diminished degree of body density—metabolic or common obesity.
3. Polysarcia associated with a lesser volume weight of the organism—hydroplasmic obesity, or lipomatous hydroplasma.

#### HYPERPLASMIC OBESITY OR LIPOMATOUS HYPERPLASMA.

Hyperplasmic obesity is the rarest type, forming, according to my notes, about 6 per cent. of all cases of corpulency. It occurs principally in male subjects, most often between the ages of 27 and 38. I have seen two or three instances of it in women. This form of polysarcia is the only one true to this name, inasmuch as the stoutness is caused by the augmentation of the body protoplasm alone. Corpulency of this type is never very pronounced; the increase in body weight but rarely exceeds 15 kilograms. The average surplus in absolute weight may be put down to 7 kilograms, about 15 pounds.

The polysarcia of this class is characterized by the following: Extreme firmness and strength of the muscles; dry skin; increased cardiac activity; high arterial tension, usually above 160 mg, Hg, by the sphygmomanometer, and high blood density. The latter amounts at least to 1064, but frequently to 1068 and above in the male, and to 1062 and 1066 and more in the female organism.\*

The volume weight of the individual attains a considerable degree, which may be ascertained by adding the coefficient to the degree of blood density. It will be found that the corporeal specific gravity in hyperplasmic

obesity is from 5 to 9 points higher than in the normal state.

This form of corpulency, not disfiguring or in itself weakening the system to any extent, demands our special attention on account of its complications. Among the latter, incipient nephritis and metabolic anomalies, as xanthemia, arthritis urtica, oxaluria are common. The one concomitant phenomenon invariably present, however, is that chronic condition which v. Basch<sup>5</sup> has designated as "latent arterio-sclerosis." The continued high blood pressure points to the existence of this condition. No other symptoms are indicative of latent arterio-sclerosis, for the moment such occur the affection is not latent any longer. The affection is not even in its incipency, as there is neither polyuria nor albuminuria, whose presence one might infer to arterio-capillary fibrosis.

At the period when conspicuous anatomic changes symptomatic of arterio-sclerosis appear, which invariably are produced if proper treatment is not early instituted, the polysarcia has been transformed from the hyperplasmic to one of the metabolic types.

Again, as hyperplasmic obesity is always accompanied by latent arterio-sclerosis, we may well assume that this is not a mere complication of the former, but a condition arising from the same factor, and at the same moment as the polysarcia itself. Viewed from this point, hyperplasmic obesity is but a symptom of a certain systemic anomaly.

#### METABOLIC OR COMMON OBESITY.

Metabolic obesity is the most frequent type, forming, according to my statistics, about 68 per cent. of all instances of polysarcia. Its frequency is greater in males than in females, the ratio being about 5 to 2. It is an affection of middle life, but is not uncommon in well-fed children. In women I have never seen a case above the age of 65, a period of life when it is rare in males.

I distinguish two varieties of metabolic obesity, viz., one kind where an increase of body protoplasm concurs with an enlarged deposition of fat, the other in which adiposis is increased without synchronous augmentation of albuminous tissue constituents.

Its characteristics in general answer to those of the plethoric form of the older writers, heretofore described. There is no or almost no discrepancy between the corporeal density in this type of polysarcia and that of the normal individual. This is especially the case when both body protoplasm and fat are increased in a similar ratio in which they occur in the normal organism. The greater the increase of fat as compared with that of albumin, the lower will be the corporeal specific gravity. The least degree of body density in this form of obesity is found in those instances where the tissue albumin is neither augmented nor reduced, and where fatty matters alone have accumulated. The volume weight in metabolic obesity varies between 1062 and 1067 in males, and between 1059 and 1066 in females. These figures are arrived at by the addition of the coefficient six to the respective blood density.

While in this, the common type of polysarcia, the surplus in absolute weight is often considerable, it does not exceed 20 or 30 kilograms in the majority of instances. However, in the United States cases of 50 and 75 kilograms surplus become more frequent from year to year, especially in the large cities, where great distances have called forth ever ready transportation facilities, which in turn have given rise to abnormal body inactivity and in many instances to corpulency.

\* A condition analogous to hyperplasmic obesity is occasionally observed in animals fattened by a special method. Müntz (Comptes Rend., Tome 112, p. 298, v. Limbeck) found a blood density of 1058 in fattened and one of 1038 in normal sheep. The dry residue of the blood of the fattened animals amounted to 20.33, that of the common sheep to 13.60 per cent.

In the same proportion in which the number of those who take their daily "constitutional" declines, the great family of the bodily unsound and the obese grows.

The chronic disorders concurrent with hyperplasmic obesity also accompany this type of polysarcia. Their presence is independent of the degree of corpulency as well as in a certain measure of its duration. However, the concurrent affections are usually more developed than in the hyperplasmic condition—latent arterio-sclerosis has yielded to incipient or pronounced arterio-capillary fibrosis; the heart in consequence is hypertrophic. The most clearly defined complications in metabolic obesity are due, to a certain extent, to the more advanced age of the patient, which, on the average, is about 10 years above that of the individual possessed of the hyperplasmic form of polysarcia. Again, the occurrence of accompanying conditions, which are almost as frequent as the main affection itself, forces us to consider metabolic obesity like the hyperplasmic type, as a mere phase or phenomenon in a general systemic deterioration.

#### HYDROPLASMIC OBESITY OR LIPOMATOUS HYDROPLASMA.

Hydroplasmic obesity is found in about 25 per cent. of all cases of polysarcia. It is most common in women and may occasionally appear at puberty. Normally, however, it occurs between the 35th and 48th year.

Among the principal characteristics of this type of obesity may be enumerated the following: Pallor eximius; flaccid adynamic muscles; wrinkled skin; flabby abdomen, inclining frequently over the genitals; low arterial tension; weak heart; low blood density; varicosis; edema, and scanty urination. The specific gravity of the organism is considerably lowered, which is evinced by the low blood density. Obese individuals whose volume weights are below 1060 in males and 1056 in women, that is, whose blood density is less than 1054 and 1050 respectively, belong to the hydroplasmic group.

We encounter here two varieties, namely, one in which the protoplasm is diminished and the fat alone increased, the other in which the loss of body albumin coincides with an increase in fatty substances and water. It is evident that the corporeal density of the obese in whom loss of albumin and increase in fat and water occurs, is somewhat higher than that of the individual of similar absolute weight in whom equal loss of tissue albumin but increase of fatty material alone had taken place.† In both eventualities, however, the volume weight would be subnormal, as the density of water is 1 and that of human fat 0.932.

The absolute weight in hydroplasmic obesity, although the patients appear exceedingly corpulent, as a general rule does not reach as high a point as in the metabolic type. An average surplus of kilograms as in the other types of polysarcia, on account of the great divergences in absolute weight in the individual cases, can not be consistently accepted.

Lipomatous hydroplasma, even in a greater measure than the other forms of corpulency, is not an independent affection, but a most conspicuous symptom of a general degenerative process. The latter is probably the same which stands at the foundation of the other classes of polysarcia. Hence, hydroplasmic obesity may be the direct and early result of a systemic degeneration, or it may be consequential to one of the other types of corpulency.

† It is doubtful whether an increase of fat material without one of water can ensue at all; the one variety is characterized by excess of water in the tissues, in the other variety the amount of water is also somewhat increased.

#### INDICATIONS FOR THE TREATMENT OF OBESITY.

All that has been heretofore stated tends to evince that obesity, irrespective of the type in which it appears, is not an affection per se, but a link only in a chain of symptoms pathognomonic of certain nutritional disorders, which in turn give rise to a slower or more rapid systemic deterioration. In so far as the amelioration of a prominent symptom is followed by an improvement in the general condition, the treatment of polysarcia, apart from some exceptions, is therefore always indicated.

As long as corpulency does not interfere with vital functions, a proper treatment is hardly ever instituted. It does not enter the mind of the otherwise still comparatively healthy obese to undergo unusual exertion or self-deprivation for the mere purpose of reducing the body weight. He does not care whether he weighs a few kilograms more, or less. Nowadays uncomplicated polysarcia, that is, where the concurrent phenomena are still obliterated and remain unrecognized, if treated at all is done for cosmetic reasons only. The vast majority of the corpulent do not consult a physician before the accompanying disorders and conditions compel them to do so. At this stage to be sure, the treatment, be it ever so well advised, can not accomplish what it would have afforded if instituted earlier in the course of the affection.

Cases of *hyperplasmic* obesity never attain the enormous increase in absolute weight which may occur in the other types. The over weight, not exceeding 15 kilograms in most instances, in itself does not call for any treatment. A surplus of from 10 to 15 kilograms in the adult well-developed individual may even be considered as within the physiologic limits, and, as a matter of fact, such individuals are accepted by the life insurance examiner. However, in hyperplasmic obesity we meet not only with an increase in absolute weight, but also with one in the specific weight of the organism. The concurrence of these factors in every instance is an indication of a systemic anomaly demanding treatment.

*Hydroplasmic* obesity, always denoting the presence of grave disturbances in the organism, irrespective of the amount of overweight in a given case, is *a priori* an indication for the institution of proper treatment.

In *metabolic* obesity, the common form, where there is no or practically no alteration in the corporeal density, treatment may not be absolutely indicated if the surplus weight is yet within physiologic range. A body weight 10 or 15 per cent. above the average may still be considered normal. In those cases, however, where the over weight exceeds 15 per cent., no matter how well the individual pretends to feel otherwise, treatment is urgent and should be insisted upon. Therapeutic measures should be taken before the concurrent affections have become too prominent a factor.

Besides old age and diabetes mellitus, there are few if any contraindications to the institution of de-adiposition.

At this point it is seasonable to mention something relating to the mean height and weight of both sexes in the different ages of life.

Guételet's figures, which are copied in all pertaining works, are based upon investigations and statistics concerning the French race and are certainly misleading if applied to the American people. Children and adults of both sexes on the average are taller and heavier in this country than are individuals of the same age in France. I have computed the appended table as follows: Height to 14th year inclusive, according to Monti<sup>6</sup>; weight to the 18th year inclusive, according to Cam-

erer.<sup>7</sup> The populations of Australia and Southern Germany present almost the identical physical characteristics. Those of the young Americans, if at all, differ but slightly. The remaining figures have been obtained partly by investigation and partly by comparisons and calculations.

AUTHOR'S TABLE DENOTING MEAN HEIGHT AND WEIGHT OF BOTH SEXES IN THE DIFFERENT AGES OF LIFE IN U. S.

| Age.        | Men.          |             |               |               | Women.        |             |               |               |
|-------------|---------------|-------------|---------------|---------------|---------------|-------------|---------------|---------------|
|             | Body, inches. | Height, cm. | Body, pounds. | Weight, kilo. | Body, inches. | Height, cm. | Body, pounds. | Weight, kilo. |
| 1. . . . .  | 28.74         | 73          | 21.78         | 9.9           | 28.50         | 72.4        | 20.24         | 9.2           |

#### GENERAL CONSIDERATIONS CONCERNING THE TREATMENT OF POLYSARCIA.

Lipomatosis universalis may have been caused directly either by excessive ingestion of nutriment or by its diminished oxidation in the organism, or by both eventualities together.

The caloric demand for the maintenance of the metabolic equilibrium is dependent upon the amount of work performed by the organism. The more the individual exerts himself, the higher must be the caloric value of his nourishment and vice versa; the greater the bodily inactivity, the less energy is expended, and the smaller need be the fuel supply of the organism.

A normal man utilizes on the average, for each kilogram of body weight per day when at absolute rest, 30 calories, of which 4.1 calories should be yielded by albumin. For each kilogram of body weight per day when leisurely occupied, 35 calories, of which 5 should be yielded by albumin. For each kilogram of body weight when moderately active, 40 calories, of which 6.1 should be yielded by albumin. For each kilogram of body weight per day when laboring strenuously, 45 calories, of which 7.2 should be yielded by albumin.

A man of 35, weighing 71.5 kilograms, for the maintenance of his metabolic equilibrium, should, therefore, consume daily an amount of foodstuffs yielding as follows: 2145 calories, of which 293.15 should be albumin calories, when at absolute rest; 2502.5 calories, of which 357.5 should be albumin calories, when leisurely occupied; 2860 calories, of which 436.15 should be albumin calories, when moderately active, and 3217.5 calories, of which 514.8 should be albumin calories, when laboring strenuously.

Roughly speaking, about the sixth part of the total

calories needed by the animal organism should be derived from ingested albumins.

The same individual having changed his boarding house, continues to take similar nourishment in quantity and quality as before. However, instead of finding boiled potatoes on the table every evening, which he was accustomed to eat by simply adding some salt, he now is served three times a week with fried potatoes. The change, trifling in itself, is hardly noticed by him, but alas, after a few months his waistcoat becomes too narrow for him and he opens at first one, and as time progresses two and more buttons during the meals. Why does he do that? The fried potatoes contain at least 20 grams of butter; one gram of butter yields 9.3 calories, the 20 grams represent, therefore, a caloric value of 186. As he is now eating this dish three times a week, the surplus in calories amounts to  $186 \times 3 \times 26$ , or 14,508 calories in six months. Almost the total surplus of 1560 grams has been deposited in the organism in the form of fat, and, as adipose tissue contains about 40 per cent. of water, the total increase in body weight amounts to 2184 grams, about 4.5 pounds. In a year the surplus body weight would be 9 pounds, and if the individual chooses to partake of fried potatoes every day for a year his body weight would be increased from 71.5 kilograms, or 157 pounds, to 81.77 kilograms, or 179.5 pounds, during that period.

Assuming, on the other hand, that this same person, who was always moderately active, retires to a life of leisure, but continues to ingest daily an amount of foodstuffs valued at 2860 calories, he introduces about 350 more calories than can normally be burned up in his body. If the non-oxidizable surplus amounts to even but 250 calories, 26.4 grams of fat are daily deposited in the organism. In a year the increase in fat amounts to 9636 grams and that of adipose tissue to about 13,488 grams, or 29.6 pounds.

Before instituting treatment for polysarcia the following factors should be therefore ascertained: 1. Age and absolute weight of patient. 2. Approximate extent of surplus adipose deposition. 3. Degree of body activity other than that essential for the conduct of vital functions. 4. Caloric value of nutriment habitually ingested.

The first step in the actual treatment should be adjustment of the ingesta in accordance with the degree of muscular activity, or regulation of the latter with regard to the amount of calories yielded by the foodstuffs habitually consumed.

When we bring home to our mind the fact that in the obese the surplus weight in the vast majority of instances is due to fat alone, or to fat and water, we can readily understand that it is no easy task to definitely determine from the number of kilograms of body weight the nutrient calories actually needed by the organism. Intracellular fat and water usually neither participate in the general systemic metabolism, nor contribute towards the performance of muscular work. On the contrary, they are an absolute ballast to the individual, predisposing him to various diseases, especially epidemic ones, and impending more or less the vital as well as the muscular activity.

In calculating the necessary calories, at least in an approximate manner, it is best to ascertain the height of the patient, and, with the assistance of the appended table, the corresponding weight in kilograms. In most cases of metabolic obesity it suffices to multiply the number of kilograms thus obtained by 25, to learn the mini-

imum amount of calories daily needed. For instance, take the case of a male, aged 35, having an absolute weight of 95 kilograms, and height of 172 cm. The normal weight corresponding to 172 cm. height is 65.5 kilograms, therefore  $65.5 \times 25 = 1637.5$ , is the minimum amount of calories necessary to prevent the consumption of body albumin in this individual.

In hydroplasmic obesity, on the other hand, when starting with the treatment, the amount of food prescribed, whether its caloric value was compiled in the aforementioned or any other manner, always remains to a great extent a matter of conjecture. This type of polysarcia, it being virtually a condition of hypotrophy, frequently demands a diet of increased nutritive—not caloric—value. Diminution of absolute weight in hydroplasmic corpulency without concurrent increase in body density as evinced by the specific gravity of the blood, denotes deficient alimentation.

Patients under treatment for obesity should have their food carefully weighed and should be seen every third or fourth day, during the first two weeks, ten at least once a week for one or two months, and after that, fortnightly for a period of from three months to a year. On each occasion the patient should be weighed on an accurate scale, and, in the hyperplasmic and hydroplasmic types, the blood density should be ascertained at least once every two weeks, while in the metabolic variety it is sufficient to take it once a month.

Equally important as the decline in absolute body weight is the degree of blood and body density during the period of treatment. The blood density serves as the means of control, whether the measures which have been taken to reduce obesity are proper or not. For instance, a woman 157 cm. high, weighing 95 kilograms, and possessing a blood density of 1050, undergoes treatment. When seen at the end of a month she complains of extreme weakness, of emaciation and pains in the back and limbs, and of palpitation of the heart on the smallest exertion. She has lost during this time 7 kilograms in body weight. An examination of the blood reveals a density of 1048, a decline of 2 degrees since starting treatment. The diminished specific gravity of the blood, congruous, as we have repeatedly seen, with a lesser volume weight, denotes that the woman was underfed. Her subjective symptoms were probably all produced by underfeeding.

We should endeavor to accomplish the following in the treatment of the different forms of polysarcia:

In hyperplasmic obesity, reduction of absolute as well as of volume weight; metabolic obesity, reduction of absolute weight and maintenance of volume weight, and in hydroplasmic obesity, reduction of absolute weight and increase of volume weight.

The well-known dietary systems of Harvey-Banting,<sup>8</sup> Ebstein,<sup>9</sup> Oertel,<sup>2</sup> (Schweninger) Kisch,<sup>10</sup> and Hirschfeld<sup>11</sup> make no or but indefinite reference to the volume weight of the organism. There is no doubt but that all these regimens serve an admirable purpose in suitable cases. However, they are not applicable in all forms and degrees of obesity. Kisch and Oertel especially have recognized this when they prescribed different diet lists for the plethoric and the anemic types of the affection.

These dietary regulations possess the drawback in common that the patient is underfed, and that the calories elaborated from the prescribed nutriment do not suffice to prevent gradual consumption of the body protoplasm. I had occasion to observe in a number of instances that after ten or twelve days' employment of certain

of these dietary systems, the amount of nitrogen egested surpassed that of nitrogen ingested. The large quantities of fat recommended in some of these regimens, although yielding large amounts of calories, may still not be sufficient to avert the loss of body protoplasm after the first or second week. The results of overfeeding can not be obliterated by systematic underfeeding. I am of the opinion that, apart from some exceptional cases, the employment of a diet valued at less than 25 calories per kilogram normal body weight, means, to say the least, unnecessary deprivation to a patient following his vocation. Cases treated according to Weir-Mitchell's or other methods of rest cure, where absolute inactivity is demanded, will undoubtedly get along with a smaller number of calories for a certain period. However, we have to deal, in the vast majority of cases, with people who are not only able but also should be up and about, and it must be our foremost aim to preserve the strength and resistance of these patients. A rational treatment of obesity can only be instituted on the basis of increased bodily exertion and oxidation and not on that of underfeeding.

There is a diversity of opinion concerning the amount of water necessary in the treatment of the obese. In the chapter on the "special management of the different types of polysarcia" the amounts of water per kilogram per day which I found best suited to keep up cellular activity to its fullest extent, are recommended for each specific form of the affection.

No mention is made in these lines of alcoholic and malted beverages. The latter are positively contraindicated in the treatment of obesity, and the former, which some modern authors permit in moderate amounts, although they possess high caloric values, I find, to say the least, entirely superfluous in the therapy of this as well as of all other pathologic states.

All measures which enhance the oxidizing qualities of the organism prevent further deposits of adipose tissue and contribute toward lipolysis. As long as the corpulent is properly fed, as long as he retains a certain amount of strength, such measures may be employed. Hydrotherapy, balneotherapy, mechanotherapy, gymnastics, etc., combined or alone, in any of their manifold variations, they all serve but one purpose—to increase the process of oxidation and the subsequent fat combustion. The selection of a mode of physical treatment when starting may be entirely left to the discretion of the patient. By permitting this the medical adviser gains the latter's good will, does not overburden him, and has no difficulty in adjusting the indicated measures later on. It requires great self-command on the part of many obese to continue and increase a certain method of exercise. This is especially the case when visible results do not immediately follow the first attempt.

Muscular exercise, whether passive, active, concentric or eccentric, is always essential in the treatment of lipomatosis. Even in cases of advanced hydroplasma, when the patient is compelled to stay in bed, massage and certain passive movements should be insisted upon. Active muscular exercise, as walking, climbing hills, rowing, boxing, bicycle riding, etc., are the most potent factors in increasing tissue oxidation. In every individual case the ability for exercise should be carefully ascertained. The patient must not be overtaxed in this respect, as this may call forth results which are analogous to underfeeding. As stated before, the patient may in the beginning select the mode of exercise which he intends to execute; his choice generally is walking on the level

ground. In cases in which cardiac asthenia is very pronounced, the form and amount of exercise to be taken is to be minutely described by the physician. In other cases, especially the metabolic variety, detailed directions are but rarely required. The amount of meters which the patient has to walk is to be increased from time to time. The robust may extend his promenade 1000 meters at a time; in the weak and hydroplasmic a gradual increase, say 100 or 200 meters at a time, will give the best results. Climbing, which may be indicated from the start for persons affected with the metabolic variety of polysarcia, should never be recommended as the initial form of exercise when the systemic deterioration has far progressed. Such cases should be handled with the greatest care—at first walks on the level and later climbing, but this in moderation only. It has been estimated that tissue combustion when climbing for the distance of one meter is ten times greater than when marching the same distance on level ground. In all instances of hyperplasmic and in many instances of metabolic lipomatosis, mountain climbing is imperative for curative purposes. In my experience, descending mountains or stairways has proven a valuable adjuvant in the treatment of polysarcia, principally in such instances where the over weight was considerable. It is true that the act of descending itself does not greatly intensify oxidation; this exercise, however, affords a most convenient means of stimulating the abdominal muscles to increased activity. The technique of descending exercise which I pursue is very simple. The patient is carried by the elevator to the fifteenth or twentieth story of an office building or other high structure. For the first week he is ordered to slowly descend the stairs, without holding to the banister, 10, 15 or 20 stories, as the case may be, from one to four times daily. During the second and third weeks this exercise is somewhat modified, the patient descends from step to step in a jumping manner, which produces a jolting of all the muscles of the abdomen. Later on the same exercise is continued, but the individual is ordered to perform it at his utmost speed. Athletic practices, so long as they do not overtax the strength or affect the heart and nervous system, are of a certain value in the treatment of all types of polysarcia. Of course proper gymnastic exercise has to be selected for each individual case. I prefer a course of calisthenics, especially such as are arranged for strengthening and developing the trunk, for they can not possibly do any harm and most of the movements may be readily executed. One of the most expedient exercises for the furtherance of systemic combustion is gymnastics of the lungs. The patient should be first taught to breathe properly. The inspiration should gradually become deeper and deeper until finally almost the whole lungs participate in the process. It is best to perform these chest-expanding exercises in the evening before retiring. I am in the habit of combining the lung gymnastics with air baths, that is, have the patient exercise while nude, and perform various muscular movements, the detailed descriptions of which I have to forego at this moment.

Besides diet and exercise a number of medicinal agents have been employed in the reduction of obesity. The following drugs and chemicals have been reputed to be anti-fat remedies: Iodin, and its preparations; phytolacca decandra; thyroid extract; vegetable acids; vinegar; lemon juice; alkaline, acidulated and sulphurous mineral waters; alkalies, as liquor potassæ; fucus vesiculosus; sodium chlorid; purgatives, and a legion more. Most of these have of late come into discredit, be

it on account of their inefficiency and uncertainty of action, or on account of certain obnoxious results following their administration. It is my opinion, however, that most of these drugs, if given in sufficient amounts, bring about reduction of body weight. They act in large doses like certain poisons, the introduction of which is followed by emaciation, loss of strength, irritability, anorexia, insomnia and often chronic diarrhea. The majority of these are useless in small doses, and in large ones do not only produce dehydration and de-adiposition, but invariably also a melting down of body albumin. Their use, with the exception of a few, should, therefore, be unconditionally condemned, especially in instances of metabolic or hydroplasmic obesity. Some mineral waters, thyroid preparations whose action is modified, and fucus vesiculosus form the exception to this rule.

It is uncertain, apart from their aperient and laxative action, what the *modus operandi* of mineral waters, as those of Marienbad, Carlsbad, Kissingen, Saratoga, and the Hungarian waters, like Apenta, really is. Their influence in the rarest instances is a chemical one. The blood is not altered in its composition, at least not for any length of time after these waters are taken. Metabolism, however, increases under their continued administration. It appears as if the salt solutions exhibit physical functions by increasing the osmotic pressure in the organism. The acceleration of metabolic processes may be the direct consequence of the latter.

Thyroid therapy a few years ago seemed to be the panacea in the amelioration of obesity. But, alas, the indiscriminate use of the glandular substance by every one who wished to effect rapid reduction of his corpulency, was frequently followed by disappointment and by bad after-effects. In the wake of self-treatment by thyroid extract I have seen glycosuria in six or seven instances. The origin of at least two chronic conditions of glycosuria which came under my observation could be traced to thyroidism. Cases of digestive disturbances, extreme nervousness, jactitation and cardiac weakness were not infrequently met with after ingestion of thyroid substance. Most of these untoward symptoms noted after the use of thyroid occurred in persons who relied upon their own mode of administration.

On account of its uncertainty of action and occasional pernicious effects, the profession has abandoned thyroid therapy to a great measure. However, this means throwing away the good with the bad. Thyroid extract is by no means a necessity in the treatment of polysarcia, but it is a valuable adjuvant if used with precaution. Especially is this the case where the treatment is started and when some immediate results are to be accomplished. The idea of having lost a few pounds in weight during the first week, as a rule, tends to renew the patient's failing energy. Later on, when the obese is accustomed to his new mode of living, the thyroid preparation may be withdrawn. Unless the patient is under a regulated diet so that he is in perfect nitrogen balance, and his tissue oxidation is somewhat increased by suitable exercise, the drug should not be administered under any circumstances. Ewald<sup>12</sup> demands even an adequate surplus of ingested nitrogen in order that the thyroid preparation may accomplish the removal of adipose tissue without doing injury to the body protoplasm.

I have modified the action of the thyroid by the addition of arsenic and adonidin, thus:

|                                 |          |     |
|---------------------------------|----------|-----|
| R. Acid arsenious .....         | gr. 1/60 | 001 |
| Adonidin .....                  | gr. 1/12 | 005 |
| Thyroid gland, dry powder ..... | gr. 2    | 12  |
| M. Ft. compressed tablet No. i. |          |     |

Six years ago I first observed that arsenic exerts a specific influence upon the activity of thyroid. Patients who took an arsenical and thyroid preparation synchronously never complained of any deleterious effects, while those who were treated with thyroid alone occasionally exhibited such symptoms as I have mentioned. So pronounced was the modifying power of arsenic that in the course of time I never prescribed thyroid preparations without adding arsenic in some form. My observations have been confirmed by those of Bédart and Mabilie,<sup>13</sup> who did not find palpitation, tremor, etc., following the administration of thyroid if Fowler's solution—2½ drops per kilogram—was given simultaneously. Adonidin is added to the combination to further strengthen the heart and enable the patient to continue the prescribed exercises.

Fucus vesiculosus (bladder wrack) I found an innocent and efficient fat absorbent to be used in conjunction with proper diet and exercise. I have devised a citric acid tincture of the drug which serves an excellent purpose in preventing the recurrence of a previous state of obesity. One of my patients, aged 35, an actress of national fame, in spite of a proper diet and a good deal of exercise, would have attained such an embonpoint that she could not have followed her calling were it not for the citric acid tincture of fucus vesiculosus which she has taken for four years. She is and has been in absolute nitrogen equilibrium, possesses great powers of resistance and carries her 85 kilograms with graceful ease.

#### SPECIAL MANAGEMENT OF THE DIFFERENT TYPES OF POLYSARCIA.

*Hyperplasmic Obesity.*—Objects to be attained: Reduction of absolute and volume weights; diminution of arterial tension, and increase of body oxidation.

Diet: There should be given for each kilogram of normal body weight during twenty-four hours of albumins 1.3 grams or 5.33 calories, carbohydrates 1.8 grams or 7.38 calories, and of hydrocarbons 1.3 grams or 12.09 calories, a total of 24.80 calories. The quantity of water should be 60 c.c. Thus for a hyperplasmic male, aged 35, absolute weight of 80 kilograms, height 172 cm. (normal weight corresponding to 172 cm., 65.5 kilograms) the calories required for the patient in twenty-four hours would be 1637.5, as follows:

Albumins, 85.15 grams, or 349 calories; carbohydrates, 117.9 grams, or 483 calories, and hydrocarbons, 85.15 grams, or 792 calories, in all 288.2 grams, or 1624 calories. The amount of water should be 3930 c.c. These 1600 calories and 4 liters of water should be divided up thus:

| Meal hours.        |  | Albumins, grams. | Carbohydrates, grams. | Hydrocarbons, grams. | Water, c.c. |
|--------------------|--|------------------|-----------------------|----------------------|-------------|
| Breakfast, 7 a. m. | 2 cups of tea or coffee, 10 c.c. fresh milk in each cup—no sugar . . . | 0.7              | 1.                    | 0.7                  | 520         |
|                    | 2 boiled eggs . . .  | 12.6             | 12.1                  | 12.1                 |             |
| 10 a. m. . .       | 35 grams rye bread, 8 grams butter                                     | 2.7              | 14.9                  | 6.8                  |             |
|                    | 2 glasses of water . . .   | 5.               | 5.                    | 5.                   | 500         |
|                    | 500 c.c. clear soup . . .  | 5.               | 7.5                   | 500                  |             |
|                    | 100 grams boiled beef . . .  | 35.              | 25.                   | 25.                  |             |
|                    | 100 grams spinach . . .  | 3.5              | 4.5                   | 0.5                  |             |
| Lunch, 1 p. m.     | 50 grams Roman salad, 5 c.c. olive oil . . .                           | 1.1              | 1.8                   | 5                    |             |
|                    | 70 grams wheaten bread . . .   | 4.9              | 39.6                  | 0.4                  |             |
|                    | 100 grams apples, fresh . . .  | 0.4              | 17.                   |                      |             |
|                    | Demitasse coffee, 2 glasses water . . .                                |                  |                       |                      | 600         |
| 4 p. m. . .        | 1 glass of water . . .   | 2.               | 2.                    | 3.1                  | 250         |
|                    | 250 c.c. clear soup . . .  | 2.5              | 3.1                   | 250                  |             |
|                    | 2 boiled eggs . . .  | 12.6             | 12.1                  |                      |             |
| Supper, 7 p. m.    | 70 grams wheaten bread, 15 grams butter . . .                          | 5.               | 39.6                  | 13                   |             |
|                    | 1 cup of tea, 2 glasses of water . . .                                 |                  |                       |                      | 750         |
| Before retiring.   | 2 glasses of water . . .   |                  |                       |                      | 500         |
|                    | Total . . .  | 86               | 118.4                 | 86.8                 | 3870        |
|                    | Calories . . .   | 352.6            | 483.4                 | 507.2                |             |

The nutriment should contain the same amount of albumins, carbohydrates and hydrocarbons for at least six months. If after six months the body weight has been diminished and the corporeal density has attained a normal degree, the caloric value of the diet may be increased from 15 to 40 per cent. However, for about one week in every month, for about one year thereafter, if need be forever, the original diet must be followed. In regard to the water, 60 c.c. in twenty-four hours, for each kilogram of body weight, should be taken till the volume weight has definitely declined to a normal degree.

Exercise.—The patient should walk two or three miles after breakfast, one mile after lunch, and three miles after supper every day. A bath at a temperature of 72 F. (22.2° C.) should be taken three times a week, preferably before retiring. This exercise is to be continued for one or two years, or a longer period.

Medicines.—From 3 to 5 of the compound thyroid tablets, as given above, should be prescribed for about ten days; thereafter 3 tablets a day for a week in each of the following five months are to be given.

*Metabolic Obesity.*—Objects to be attained: Reduction of absolute weight; maintenance or increase of corporeal density; diminution of arterial tension, and increase of bodily oxidation.

Diet.—For each kilogram of normal body weight for twenty-four hours there should be taken of albumins 2.6 grams or 10.66 calories; carbohydrates 1.6 grams or 6.56 calories; and of hydrocarbons 0.8 grams or 7.44 calories; making altogether 24.96 calories. The patient should drink in that time 45 c.c. of water. Therefore a male, aged 35, affected with metabolic obesity, whose absolute weight was 90 kilograms and height 172 cm. (normal weight corresponding to 172 cm., 65.5 kilograms), should have in twenty-four hours 1637.5 calories, as follows: Albumins, 170.3 grams, or 698 calories; carbohydrates, 104.8 grams, or 430 calories; hydrocarbons, 52.4 grams, or 487 calories; in all 327.5 grams, or 1615 calories. The amount of water to be 2947 c.c. These 1600 calories and 3 liters of water should be divided up thus:

| Meal hours.        |  | Albumins, grams. | Carbohydrates, grams. | Hydrocarbons, grams. | Water, c.c. |
|--------------------|--|------------------|-----------------------|----------------------|-------------|
| Breakfast, 7 a. m. | 500 c.c. milk, heated to 100° F . . .        | 17               | 24.                   | 18.3                 | 440         |
|                    | 71 roll, 30 grams . . .                      | 2.6              | 19.                   |                      |             |
| 10 a. m. . .       | 250 c.c. buttermilk . . .                    | 10.              | 9.                    | 0.7                  | 230         |
|                    | 500 c.c. clear soup . . .                    | 5                | 7.5                   | 490                  |             |
| Luncheon, 1 p. m.  | 300 grams roast beef, very lean . . .        | 100.             | 7.5                   |                      |             |
|                    | 250 grams asparagus, little vinegar . . .    | 4.5              | 6.5                   | 0.5                  |             |
|                    | 30 grams wheaten bread . . .                 | 2.1              | 17.                   |                      |             |
|                    | Demitasse coffee, 2 glasses water . . .      |                  |                       |                      | 600         |
| 4 p. m. . .        | 1 glass of water . . .                       |                  |                       |                      | 250         |
|                    | 250 c.c. bouillon with 1 egg . . .           | 8.8              | 9.7                   |                      | 250         |
|                    | 30 grams hand cheese . . .                   | 10.9             | 1.7                   |                      |             |
| Supper, 7 p. m.    | 250 c.c. skimmed milk . . .                  | 8.1              | 11.6                  | 2.5                  | 230         |
|                    | 30 grams wheaten bread, 5 grams butter . . . | 2.1              | 17.                   | 1.2                  |             |
| Before retiring.   | 2 glasses of water . . .                     |                  |                       |                      | 500         |
|                    | Total . . .                                  | 171.1            | 101.1                 | 52.6                 | 2970        |
|                    | Calories . . .                               | 701.5            | 426.8                 | 489                  |             |

A nutriment of the same caloric value and possessing the various ingredients in similar proportion, I find best suited for both varieties of metabolic polysarcia. This dietary should be kept up as long as possible, in no instance for less than three months. The purpose of a regimen, like that of the whole treatment advocated, is rather to effect physiologic reduction of obesity than rapid cure of it. It is evident, therefore, that the stricter and longer the diet is adhered to, the better and more lasting will be the results obtained.

Water.—The variety of metabolic obesity characterized by normal volume weight, where we have an increase of protoplasm together with fat, demands each day about 45 c.c. of water per kilogram of normal body weight, and this for a protracted period. In the other variety, where the deposition of fat alone is enlarged, the amount of water should be reduced to 30 c.c. a day per kilogram of normal body weight between the third and fourth weeks, and to 20 c.c. per day for each kilogram normal weight after two months. Soups and milk have then to be abandoned, partially or altogether, and the amount of nutrient thus withheld should be replaced by eggs or meats. However, for one week in each month, 45 c.c. of water a day per kilogram of normal body weight should be taken. Scales and hydrometer, as pointed out before, are to be employed whenever possible. Loss in absolute and increase in specific weight, denotes the effect of diet in the latter variety of metabolic obesity. In some of these cases, it is true, partial withdrawal of water from the onset of treatment will give quicker results, but the tendency to arthritis urtica, etc., especially when under such a highly albuminous dietary regimen, must always be taken into due consideration.

Exercise.—There is no type of polysarcia in which exercise in its various modifications is so much indicated as in metabolic obesity. A diet valued at 25 calories a day per kilogram of normal body weight is just sufficient to prevent underfeeding. Without a proper amount of exercise, therefore, such a nutriment may avert further increase in body weight, but it does not call forth the desired decrease, at least not in instances of highly-developed obesity. The cases in which augmentation of fat is proportionate to that of protoplasm in the greater part, require similar exercise to those of hyperplasmic obesity. But we have seen that the degree of polysarcia of the latter type is rarely as high as that of the metabolic corpulency, and, in the degree in which the obesity is more pronounced, the amount of exercise must be increased.

Walking, climbing hills, rowing, bicycle riding, boxing, wrestling, etc., each and all may be advantageously utilized. When beginning treatment the mode and amount of exercise may be left to the inclination of the patient. Later on, however, the exact amount of exercise has to be adjusted to the needs of the organism from week to week. It is best to start with the amount of exercise recommended for the hyperplasmic type and to increase gradually so that the patient may lose from one to three pounds a week. In the ratio in which the absolute weight declines the amount of exercise must be increased or diminished. The nearer the body weight approaches the standard, the less exercise should be taken; yet daily walks of prescribed lengths should continue to be taken even after the individual has attained a normal weight.

There are always cases of this class which, to all appearances, do not yield, where exercise and diet in the beginning of treatment do not seem to exert the slightest influence upon the body weight. Nevertheless, I have not seen a single instance in which proper treatment ultimately failed. The latter must not be discontinued under any circumstances. The results will be obtained, in the one case, soon, in the other, later.

The variety of the metabolic type in which there is an accumulation of fat only, in respect to exercise, should be managed on somewhat different lines. There are cases in which, as we may assume, *a priori*, the heart is always more or less involved. Although this may not be determinable without difficulty in every instance, I usu-

ally start with the descending exercise described heretofore. After the first or second week calisthenics are recommended, at first such movements as tend to strengthen the lower extremities, later such as are designed for the upper extremities and the trunk itself. At the same time gymnastics of the lungs should be insisted upon. After the third week walking in moderation should be begun. This is to be gradually increased and climbing or rowing may be added after another month or so. Calisthenics and the like should not be discontinued, but should be executed every evening before retiring. Resistance exercises should be only resorted to where the condition of the heart peremptorily prohibits any other movements.

The hydrotherapeutic measures, Turkish, Russian and Nauheim baths, deserve consideration in suitable cases. Baths at 86 F., with or without salt, also sea baths during the heated season, as a rule, may be indulged in *ad libitum*.

Medicines.—For the variety in which protoplasm and fat is increased, compound thyroid tablets, 3 or 4 a day, for two or three weeks, should be taken; then continued in the same dose at intervals of two weeks for one week at a time, and to be continued for from three to six months. For that variety in which fat alone is increased, compound thyroid tablets, 3 a day, for eight or ten days. Thereafter 2 tablets every other day for a month.

*Hydroplasmic Obesity*.—Objects to be attained: Reduction of absolute weight; increase of corporeal specific gravity; augmentation of tissue oxidation, and increase of cardiac tonus.

Diet.—Per kilogram of normal body weight for 24 hours should be of albumins 3.4 grams or 13.94 calories, carbohydrates 1.6 grams or 6.56 calories, and of hydrocarbons 0.5 grams or 4.65 calories, a total of 25.15 calories. The amount of water should be 20 c.c. Thus a female, aged 35, affected with hydroplasmic obesity, whose absolute weight was 87.5 kilograms, height 159 cm. (normal weight corresponding to 159 cm., height 56 kilograms), requires in twenty-four hours 1400 calories, as follows: Albumins, 190.4 grams, 781 calories; carbohydrates, 89.6, 367 calories; hydrocarbons, 28 grams, 260 calories; a total of 308 grams, or 1408 calories. The amount of water should be 1120 c.c.

These 1400 calories and 1100 c.c. of water should be divided up thus:

| Meal hours.                   |   | Albumins, grams. | Carbohydrates, grams. | Hydrocarbons, grams. | Water, c.c. |
|-------------------------------|---|------------------|-----------------------|----------------------|-------------|
| Breakfast, 9 a.m.             | 150 c.c. tea, without milk or sugar.  | 46.              | ...                   | 3.1                  | 150         |
|                               | 125 grams cold lean roast beef  | ...              | ...                   | ...                  | ...         |
|                               | 40 grams dry toast, 60 grams wheaten bread untoasted  | 4.               | 34.                   | 2.                   | 150         |
|                               | 150 c.c. clear soup.  | 1.5              | ...                   | 1.2                  | ...         |
|                               | 6 oysters, blue points—60 grams.  | 5.4              | 3.8                   | ...                  | ...         |
| Luncheon, 12 m.               | 200 grams boiled, broiled or roast meat—very lean   | 70.              | ...                   | 5.                   | ...         |
|                               | 500 grams vegetables (Brussels sprouts, savoy, red or white cabbage, spinach, cauliflower, string beans, asparagus, prepared without flour or fat), average | 13.4             | 24.5                  | 1.8                  | ...         |
|                               | 170 c.c. lemonade, 1 lemon and 3 grams sugar  | ...              | 3.                    | ...                  | 170         |
|                               | 150 c.c. coffee, without milk or sugar  | 33.3             | ...                   | 2.3                  | 150         |
|                               | 90 grams cold beef  | 12.6             | ...                   | 12.1                 | ...         |
| 3:30 p.m.                     | 2 eggs.   | 3.               | 24.6                  | ...                  | ...         |
| Supper, 7 p.m.                | 50 grams rye bread.   | ...              | ...                   | ...                  | 150         |
|                               | 150 c.c. tea.   | ...              | ...                   | ...                  | 150         |
| On retiring and during night. | 150 c.c. water.   | ...              | ...                   | ...                  | ...         |
|                               | 200 c.c. water.   | ...              | ...                   | ...                  | 200         |
| Total . . . . .               |   | 189.2            | 89.9                  | 27.5                 | 1120        |
| Calories. . . . .             |   | 775.7            | 368.6                 | 255.8                | ...         |

A nutriment very abundant in albuminous material is best suited for instances of hydroplasmic obesity. The calories elaborated and yielded by the proteids should surpass both those derived from the carbohydrate and hydrocarbon ingesta together. While in the normal state but the sixth part of all calories should have emanated from nitrogenous substances, more than half of the total heat units in hydroplasmic polysarcia must be liberated by that source. The ratio of carbohydrates to hydrocarbons in this specific diet in physiologico-chemical respects is immaterial; for practical purposes, however, in order to facilitate the continued ingestion of large amounts of proteids, the absolute weight of the carbohydrates should exceed that of the hydrocarbons at least three times. A diet offering this composition should be continued for months, or, if need be, years. It contains, on the one hand, sufficient elements for the protection of or even increase of the body albumin, and, on the other, not enough of that kind of material which prevents disintegration of adipose tissue.

That proteids are the rational nutriment in this condition is evinced by the increased heart action following their supply. When the circulatory apparatus again performs its functions with sufficient vigor the body density will soon attain a normal degree. The decline of body weight in this form of polysarcia is of secondary consideration, the most potent factor to be accomplished is increase of body density. The patient, after being properly treated for some months, may present a totally different appearance. His rotundity may have disappeared, his cheeks may have sunken in, and in spite of these facts he may have lost but a few kilograms in absolute weight. His muscular system, in the meantime, has become firmer, while fat and water have slowly disappeared. The patient in this condition, being no longer hydremic, belongs to the second variety of metabolic obesity, and, although the diet for hydroplasmic polysarcia should be continued for a more or less protracted period, the exercises designed for that variety should be employed in order to gradually effect the reduction in absolute weight.

Water.—The relative great quantity of water contained in the hydroplasmic organism, *a priori* contraindicates the introduction of much liquid. The amount of water necessary per day and kilogram was estimated by the writer to be 20 c.c. A still more limited water supply, as is recommended by some authorities, I admit is followed by the rapid loss of a few kilograms of body weight. However, this occurs by dehydration only, while the fat deposits themselves are not altered. Total withdrawal of liquids, as shown by Niederstein,<sup>14</sup> is followed by decline in body weight. The latter increases soon after water is again taken. The early increase after the taking again of liquids, is due to the retention of water. The artificial and rapid concentration of blood serum and other body fluids may cause emaciation by starvation, but is certainly not followed by a physiologic reduction. The elimination of water from the tissues can be successfully accomplished—successful in the sense of removing the underlying cause—by but one means, the increased tonicities of the heart. By rapid concentration of serum the latter will never be realized. A certain amount of water is necessary in order that the tissues derive the utmost benefit from the organic as well as the inorganic ingesta.

Exercise.—As already pointed out, the exercise devised for the second variety of metabolic obesity serves well in this form of polysarcia, provided that the individual, by dietary treatment and by exercise described

in the following, has already attained a more normal degree of density.

In starting treatment most stress should be laid on passive and resistance movements. Faradism, massage, mechanotherapy, in short, all methods contributing toward the improvement of the circulation will be followed by most beneficial results. The employment of cold hydropathic procedures, resulting in increased oxidation of fatty material, and the systematic performance of lung gymnastics, are other suitable means in the combatment of hydroplasmic obesity.

Medicines—For the heart, strychnin; for the blood, iron, and for the intestinal tract, beta naphthalin, bismuth salicylate or hydrastis canadensis. To relieve constipation, saline enemata, podophyllin, leptandrin or calomel may be given.

Thyroid, as a general rule, is contraindicated in hydroplasmic obesity.

## THE MODERN SUBJECTION OF SCIENCE AND EDUCATION TO PROPAGANDA.\*

PROF. WM. T. SEDGEWICK.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY,  
BOSTON.

One of the sad pages in the history of science and education is that which relates how, on the death of Alexander the Great, the teacher of his youth, the much greater Aristotle, rightly regarded by the Middle Age as the "master of those who know" when more than sixty years old was driven from Athens into exile by a patriotic propaganda of the anti-Macedonians. A darker and a bloody page tells how Hypatia of Alexandria, the beautiful and learned daughter of Theon, was cruelly and brutally murdered in a Christian church in the year 415 of our era as a victim of a fanatical propaganda against paganism, condoned, if not conducted, by the Christian Archbishop Cyril, Patriarch of Alexandria. Copernicus hesitated long before publishing his splendid discoveries on the movements of the heavenly bodies and the heliocentric theory, for fear of ecclesiastical interference, and when soon after Galileo, more bold, promulgated the truth that Copernicus had hesitated to pronounce, both he and his discoveries fell under the severest ecclesiastical condemnation ever visited upon any man of science for the truth alone.

In our own time we have too often heard of sects which place the propaganda of a special faith before either science or education, and inquire more carefully into the orthodoxy of professors and pupils than into their scientific or educational attainments. However much we may regret such action we can not legitimately complain so long as the sectarians in question confine their actions to sectarian schools, colleges

\* Abstract of the President's Address delivered before the American Society of Naturalists, Jan. 1, 1902.

and universities, supported exclusively by private means, for the right to regulate education within the home, the family, the private school or the private college or university, is a fundamental and inalienable right of a well-regulated democracy.

The century just closed has witnessed a remarkable liberation of natural science and education from dogma. Geology was first set free by Lyell and his school, and then biology, by the discoveries of fossil man, and the splendid inductions of Darwin. Slowly but surely the teaching of natural science, which, like all teaching, follows closely in the footsteps of discovery, has also cast off its chains and freed itself from the subjection of theology. But as the church has declined in temporal power the state has become supreme, and with the recognition of its power has come the belief in its sufficiency—even its sufficiency to remedy all ills, real or imaginary—and scarcely had science and education freed themselves from the bonds of the church before they began to be threatened with subjection by the state, a subjection sought for not by theologians but by philanthropists and philozoists.

#### THE ANTIVIVISECTION MOVEMENT.

The first in the field were the philozoists, commonly known as antivivisectionists. In former times charges of cruelty brought against scientific men would have been referred to an inquisition when such an institution existed, but now, the church being powerless in such matters, appeal must be had to the state. Accordingly, a propaganda was started, first, so far as I am aware, in England, but afterwards spreading to this country, which by 1875 had succeeded in bringing into complete subjection in Great Britain animal physiology, then the principal experimental biological science. Since that time a new biological science, bacteriology, has sprung up and found itself hampered also in some of its most important and most humane investigations by the same British statute, enacted on demand of the philozoic propaganda.

Anyone may read in the 29th chapter of the admirable *Life and Letters of Professor Huxley*, edited by his son, how, in 1870, when president of the British Association, Huxley had been violently attacked for speaking in defense of Brown-Séquard, the French physiologist, and how in the same year a committee had been appointed by the British Association, and reported upon the conditions under which they considered experiments on living animals justifiable. When legislation seemed imminent Huxley, in concert with other men of science, interested himself in drawing up a petition to Parliament to direct opinion on the subject and provide a fair basis for future legislation. A Royal Commission was finally appointed, with Huxley as one of its members. Early in 1876 the Commission reported and a few months later Lord Carnarvon introduced a bill entitled "An Act to amend the Law relating to Cruelty to Animals." "It was," says Mr. Leonard Huxley, "a more drastic measure than was demanded. As a writer in *Nature* (1876, page 248) puts it, "The evidence on the strength of which legislation was recommended went beyond the facts, the report went beyond the evidence, the recommendation beyond the report, and the bill can hardly be said to have gone beyond the recommendations, but rather to have contradicted them."

Looking back over more than twenty-five years of the practical working of this law we can affirm without hesitation that under its operation both physiological science and physiological education have been kept by the state, or rather by the propaganda which secured the passage of the statute, under a needless and injurious subjection.

In Massachusetts repeated attempts have been made to secure legislation "regulating" vivisection. An antivivisection propaganda is constantly maintained in Boston, and for several successive years bills aiming at the "restriction" or "regulation" of vivisection have been introduced into the legislature by the propagandists, but, having been vigorously opposed by medical and scientific men powerfully aided by such public-spirited citizens as the president of Harvard University, the president of the Massachusetts Institute of Technology and the Bishop of Massachusetts, they have hitherto failed ignominiously. All sorts of restrictions have been suggested, and in the latest bill it was proposed to endow the agents of any society for the

prevention of cruelty to animals with powers of entrance and search, so that they might visit any laboratory at any time, taking names and otherwise interfering with the freedom of research and instruction, as well as infringing upon the individual liberty of persons engaged in experimentation upon animals. If such a law had been passed, the subjection of science to propaganda in Massachusetts would to-day be even more complete and more intolerable than it has been in England since 1875.

I need not recount the recent attempt of those engaged in this propaganda to secure restrictive legislation for the District of Columbia. Suffice it to say that the attempt was one of the boldest and most dangerous attacks upon the freedom of research which has ever been made in America.

Nor is this all. Some of those engaged in the antivivisection propaganda seek, at the same time that they would abolish vivisection, to do away with all dissection of whatever sort in public schools of whatever grade. No one in his senses desires vivisection in the public schools except, perhaps, in normal schools devoted to the education of teachers. But dissection of clams, oysters, lobsters, starfish, sea-urchins, worms, snails and possibly fishes and frogs, are not only not necessarily out of place but may even be very useful and desirable in high schools and normal schools. My own feeling is that in grammar schools and all schools lower than high schools instruction should be confined almost wholly to the external structure of plants and animals, with their occurrence, habits, habitats and the like; but I see no good reason why in high schools and normal schools the elements, at least, of the internal structure of invertebrates and even of certain vertebrates may not well be taught. I have taken some pains to secure upon this point the opinion of a number of teachers of natural science in normal schools, most of whom have also been teachers in schools of lower grade, and with one or two exceptions I find they are strongly of the opinion that a moderate amount of dissection is not only desirable but almost indispensable.

Yet in 1895 the American Humane Association published in Chicago a report on vivisection and dissection in public schools, in which various excellent persons unhesitatingly affirmed that dissection in public schools is superfluous, and that physiology can be well enough taught by means of manikins, pictures and the like. In particular, several bishops, apparently regarding themselves as qualified to give evidence on this subject, stated without hesitation that all that is necessary in the practical teaching of physiology is illustrated books, manikins, etc., some even going further and saying that dissection must inevitably blunt the sensibilities and corrupt the character of the young. Cardinal Gibbons, of Baltimore, however, was more cautious when he said: "I am inclined to think that sufficient instruction can be imparted by the use of illustrations and manikins. I think it advisable to give children the knowledge, as Scripture does, of the God-given power of man over the lower forms of life; but they should be warned that this power is not absolute, arbitrary or cruel." In reading the pronouncements of the American bishops referred to, one is reminded of the occasions for Huxley's frequent and contemptuous sneers at the bishops of his own land with whom he so often did battle with delight.

This perhaps is as good a place as any in which to urge upon all those within sound of my voice, or before whom this subject may come upon the printed page, and who desire to keep intact the freedom of science and education, the necessity of watching, in season and out of season, to repel the attacks of that propaganda which would not only compel all practical instruction in physiology to be based upon pictures and manikins, but would also prohibit altogether all experimentation upon animals, whether in physiology, bacteriology or experimental medicine. Science in Great Britain, as has already been stated, has been brought under an almost intolerable subjection by the antivivisection propaganda. In America, though long threatened, this has not yet come to pass; but unless naturalists everywhere are on their guard they will some day be taken by surprise, very much as the English naturalists seem to have been, and be brought under a similar subjection to the same hostile propaganda.

## TEMPERANCE PHYSIOLOGY.

But if in America we can rejoice that we have thus far resisted the onslaughts of philozoists upon experimental science, we must confess with sorrow that we have been less fortunate in dealing with philanthropists, in an important department of elementary education. When, in 1842, Horace Mann published his still excellent essay on "The Study of Physiology in Schools," he seems, judged by recent school statutes of the several United States, to have made one serious omission, for he nowhere mentions or even foreshadows that remarkable creation of our own times, "temperance physiology," and very likely with some old-fashioned people of to-day, he regarded temperance as chiefly a moral question.

The discovery of this new and entirely modern branch of "science" and "education" seems to have been the joint work of Dr. (afterwards Sir) Benjamin W. Richardson, of England, an able but erratic physician, and Mrs. Mary H. Hunt, formerly of Hyde Park, Massachusetts, and now of Boston. At any rate, Mrs. Hunt refers to Dr. Richardson as the author from whom she drew some of her original inspiration, but her own achievements, in organizing and directing the propaganda now associated with her name, have so far outrun anything done for it at the outset by Dr. Richardson that we must regard her, and not him, as the true creator of this astonishing movement. Mrs. Hunt says that her mind was turned to the subject in the early seventies and that she soon found in Dr. Richardson's "Cantor Lectures on Alcohol in Its Relation to Man" the exact data she had been groping for. These lectures seemed to her to prove "the dangerous difference between the demonstrated fact that it is the nature of a little alcohol to create an uncontrollable appetite for more, and the popular idea of the harmlessness of using alcohol in small quantities," and the corollary seemed to her to be "that intemperance could never be prevented until the people were taught to really know the effects of alcoholic drinks, and that this must be done through the schools." From 1880 until the present time this really remarkable woman has given her life with intense devotion and extraordinary success to a national, and even world-wide, propaganda of her faith.

The movement is variously called "scientific temperance instruction," "temperance physiology" or "physiological temperance," and it has now grown to such proportions and has gained such power as to dominate, almost absolutely, all instruction in elementary physiology and hygiene in America. It is of course right and proper that pupils in all grades of the public schools should be taught the dangers of alcoholic beverages as fully and as earnestly as other dangers lurking in food or drink. We may even grant that more stress should be laid upon this subject than upon some others. But an examination of the present status of elementary education in physiology and hygiene in the United States shows that in many cases the instruction demanded by this propaganda, and given according to law, in reference to alcohol goes much further. It even appears that all instruction in physiology and hygiene in the public schools has passed to a great and unjustifiable extent into the virtual control and under the subjection of the "temperance physiology" propaganda. Mrs. Hunt, as early as 1888, boldly announced: "We are the recruiting officers, and the teachers the drill-masters, for training the coming total-abstinence army that is to banish alcohol from human beverages."

Authoritative sources of information for testing these statements are easily accessible to all. They consist of the statutes of the several states requiring instruction, often of prescribed and peculiar kinds, regarding alcohol; of the text-books on elementary physiology and hygiene actually in the hands of the pupils; of the teachers—many of whom groan in spirit even when they do not dare to complain openly; and last, but not least, of the boastful "histories" of the propaganda prepared by Mrs. Hunt herself and published, one in 1891 (or earlier) and the other in 1897.<sup>1</sup>

From these latter it appears that largely through her personal efforts statutes now exist in nearly every one of the United States requiring instruction in physiology and hygiene with special reference to the nature and effects of alcoholic drinks; that in some states a penalty clause is attached for non-enforcement; that in some the amount of space to be given in text-books is prescribed, and in the same or in others, the time to be devoted to the subject. In some states it is also required that the subject shall not be treated in an appendix, or in a separate chapter at the end of the book.

In 1897 Mrs. Hunt<sup>2</sup> stated that "a combination of the Illinois law with the penalty [clause] of the New York law would be an ideal statute." It is therefore easy to see at what she aims, for the Illinois law requires that all pupils "below the second year of the high school and above the third year of school work" counting from the lowest primary, "shall be taught and shall study this subject every year, from suitable text-books in the hands of all pupils, for not less than four lessons a week, for ten or more weeks of each year." For students below the high school "such text-books shall give at least one-fifth their space," and for high-school students "not less than twenty pages, to the nature and effects of alcoholic drinks and other narcotics. The pages on this subject in a separate chapter at the end of the book shall not be counted in determining the minimum." The New York law of 1896 is very lengthy and likewise contains an important provision that "this subject must be treated in the text-books in connection with the various divisions of physiology and hygiene, and pages on this subject in a separate chapter at the end of the book shall not be counted in determining the minimum."

The effect of these peculiar laws closely defining instruction in physiology and hygiene has been to create a correspondingly peculiar class of text-books. Some of these have been prepared by competent writers, but most of them are inferior and some are distinctly bad. One chapter in Mrs. Hunt's "History" is entitled "The Text-Book War." It is not agreeable reading, either for scientific men or for educators. In a so-called "Great Petition to Publishers," which reads more like a threat than a petition, it is stated: "This is not a physiological, but a temperance, movement. In all grades below the high school this instruction should contain only physiology enough to make the hygiene of temperance and other laws of health intelligible. Temperance should be the chief and not the subordinate topic, and should occupy at least one-fourth the space in text-books for these grades." In the same "Great Petition to Publishers" we find it also stated that "Those text-books that are largely physiology with a minimum of temperance matter . . . do not meet the requirements of the law, and do not satisfy those who secured its enactment, and are determined to secure its enforcement." Further on, publishers are told exactly what is wanted, in great detail and in no uncertain tones.

Text-books conforming with these requirements of the propaganda may be officially "indorsed" by a "Committee of the Advisory Board" sitting in council for the purpose. In another chapter, entitled the "Text-Book War Over," it is stated that "in response to the Great Petition most of the publishers have expressed the desire to have their books revised, on condition that the National Superintendent of the Scientific Department of the Woman's Christian Temperance Union would revise them or supervise their proposed revision." That is to say many publishers were naturally eager to have their books "indorsed" by Mrs. Hunt, doubtless hoping thereby to increase their sale. On August 10, 1888, Mrs. Hunt "with secretaries and helpers returned to Hyde Park, Massachusetts and opened again 'Hope Cottage' which became the local base of operations for text-book revision." "That these revised books might be distinguished at a glance from the un-revised and unworthy books a committee was chosen \* \* \* to indicate upon each its character. \* \* \* The position

1. "A History of the First Decade of the Department of Scientific Instruction in Schools and Colleges of the Woman's Christian Temperance Union." By Mary H. Hunt, Superintendent for the United States and the World's W. C. T. U. Second Edition. Boston, 1891.

2. "An Epoch of the Nineteenth Century. An Outline of the Work for Scientific Temperance Education in the Public Schools of the United States." By Mary H. Hunt, National and International Superintendent of the Department of Scientific Temperance Instruction, and Life Director of the National Educational Association, Boston, 1897.

of the chairman (Mrs. Hunt) of this committee chosen to extend the indorsement to school text-books of this kind in behalf of the signers of the Great Petition to Publishers and of the Woman's Christian Temperance Union has proved a very trying one and a most severe test of loyalty to principle."

I may remark in passing that one is frequently reminded in Mrs. Hunt's 'histories' that the United States Commissioner of Education is, or was, a member of the Advisory Board which has conducted this remarkable propaganda. As to the propriety of the Commissioner's connection with this movement, I make no comment.

It would be tedious, though not uninteresting, to give many more quotations from the extraordinary documents which recount the history of the "scientific" temperance movement. Those who desire to inform themselves more fully should not fail to consult the original authorities referred to above. As an illustration of the almost hysterical scenes accompanying the work of securing favorable legislation by this particular propaganda, I can not forbear quoting the "Report of an Eye-Witness" describing the passage of the Pennsylvania law: "As the work of widening the temperance sentiment goes on we come now and then, would that it were more frequently, to the place where the only thing to do seems to be to raise an Ebenezer, and the only thing to say is 'Hitherto hath the Lord helped us.' \* \* \* Upon a great tide of womanly support that buoyed her up on wave after wave of prayer and of faith in her powers, has the leader of this work (Mrs. Hunt) been borne from city to city like a brave ship, laden with the treasure of knowledge and blessing to be spread out before the listening people. \* \* \* Then follows a description of the State Capitol, and of the gathering legislators, of their good-natured reception of Mrs. Hunt, of her address and its effect, after which the writer passes on to the opening of a following session: "Almost before the amen of the opening prayer had been uttered, a dozen members were on their feet offering the petitions sent in from their various districts in behalf of the bill for 'scientific temperance education'; the dozens swelled to scores, and the scores multiplied all in a moment, until so many boy-messengers were flying down the aisles with the papers, and so many arms were waving in the air, that from every seat there seemed suddenly to have sprung a great fluttering, white blossom of petition. \* \* \* I make no mistake when I call Mrs. Hunt the mother of the bill. \* \* \* Behind this mother of the bill stood some of those who have borne it so closely upon their hearts that they may properly be called its god-mothers, its sisters, its cousins and its aunts." The bill was passed and signed by the Governor and the writer remarks, "It was a God-given victory and to Him be all the praise."

One of the humors of the passage of a national law requiring "scientific" temperance instruction at West Point, at Annapolis, in the District of Columbia and for all schools under Federal control, was a debate in the Senate in which "A certain senator declared that 'rum-sellers or patrons of rum-sellers have as good right to have their views on temperance education printed by the National Government as any woman. \* \* \* The following extract," says Mrs. Hunt, "from a letter a lady from his own State wrote that senator is a fair illustration of the reception his ideas received among his constituency: 'When I knew you, sir, in our state, you were a chivalric Southern gentleman. Imagine my indignation at the audacity of the reporter who dares to report you as saying that "liquor men have as good a right to be heard in the Congress of the United States on the education of the children as any lady. \* \* \* I am sure you must be misrepresented, for no man who would say such a thing in the National Senate could represent a white man's government from this State.'" "Many such letters," adds Mrs. Hunt, "reached that senator, and thus his opposition died."

No wise educator who has given any attention to the subject can deny that the influence of this powerful propaganda has been in most respects injurious to the proper teaching of physiology and hygiene in the lower schools. Teachers, principals, superintendents, and even school committees, are seldom

able to speak with perfect frankness on the subject, from fear of the influences which may be brought to bear against them or of the intemperate criticism to which they may be exposed; and in my opinion it is time for a body of scientific men like the American Society of Naturalists or the American Association for the Advancement of Science to put on record its opinion that the subjection under which science and education are to-day suffering from the "temperance physiology" propaganda has become intolerable.

It is a notorious and a disgraceful fact, that, apparently with a view of pleasing this self-constituted oligarchy, some writers have even made alcoholic instruction the beginning, the middle, and the end, of their text-books. Of such books it may truly be said that they have no permanency of their own, and are only with difficulty preserved by alcohol.

What I have said thus far of this subject applies mainly to elementary education; but those who have witnessed the virulent attacks upon a conscientious chemist and physiologist, who has recently made important physiological experiments upon the oxidation of alcohol within the human body, because his experiments have seemed to confirm the earlier statements that alcohol in minute quantities is more like a food than a poison, do not need to be told that this same propaganda is quite as eager to bring science, as it has already brought education, under its powerful dominion. Signs are not wanting, however, which indicate that its control has already reached its climax, and even begun to decline.

An attempt in 1899 on the part of Mrs. Hunt and others to make the Massachusetts law conform more closely to the ideas of those interested in "scientific temperance" was stoutly resisted by the Massachusetts Medical Society, as well as by various scientific men and educators, with the result that the statute of 1885 remains unchanged. This prescribes that "physiology and hygiene, which in both divisions of the subject shall include special instruction as to the effect of alcoholic drinks, stimulants and narcotics on the human system, shall be taught as a regular branch of study to all pupils in all schools supported wholly or in part by public money, except special schools maintained solely for instruction in particular branches, such as drawing, mechanics, art and like studies." With the exception of the clause "to all pupils" this statute is not unreasonable, for, as I have said above, it is right and proper that the youth of the land should be taught, plainly and thoroughly, the dangers which lurk in alcoholic drinks, in narcotics, etc. What is unnecessary and objectionable is that the exact amount of such teaching should be prescribed by law; and that the method of teaching (by text-books in the hands of the pupils), the space devoted to it, and its treatment, in text-books, should be legally regulated. That, in addition, the particular text-books used should be largely determined by a self-constituted and unofficial oligarchy, leaders of a propaganda, which, in any right use of the terms, is neither educational nor scientific, is both odious and intolerable.

In Connecticut, in 1901, a statute of the objectionable sort referred to above was repealed, and one to which but little exception can be taken was enacted in its place. It is gratifying to note, also, that the Department of Superintendence of the National Educational Association, at a meeting in Chicago in the early part of the same year, adopted a report containing the following significant, if guarded, paragraphs:

"The questions of highest importance for teachers and superintendents of schools to consider [concerning 'temperance physiology'] are those which relate to the methods by which temperance instruction shall be imparted, the extent to which it shall be carried, and the subject-matter to be presented.

"The educational side of this question is vitally important, and demands thorough and systematic study."

This action is timely and welcome in view of the existence of opinion like the following, expressed in a letter to me by a representative of a prominent publishing house: "I feel that we can not be too emphatic in expressing sympathy with your movement and in denouncing the intimidation of teachers and other educators which has gone on for some years. The whole so-called temperance physiology movement of the

W. C. T. U. seems to have fallen into the hands of blackmailers and schemers, who pull the wool over the eyes of the rank and file of the organization and work both schools and publishers for their own financial benefit. You are quite right in saying that the school teachers are bullied; they are, and they do not dare resent such action as it should be resented."

Time fails me to deal, as I would be glad to do, with other forms of propaganda which seek to bring under their special subjection various departments of science or education. One of these is that known as the anti-vaccination movement, which is widely supported not only in England, but of late also in America, and has already succeeded in both countries in modifying very materially those requirements of compulsory vaccination indicated by science, experience and common sense. It is true that compulsory vaccination should be undertaken only after the most careful consideration, for it constitutes a serious trespass upon the fundamental right of personal and individual liberty. But I have no idea that this movement will ever seriously subvert the cause of vaccination, for the reason that a lively epidemic of smallpox will generally bring the majority of the people to their senses, and such epidemics are tolerably sure to come if anti-vaccinationists become too numerous or too active. I must, however, enter a protest against those medical practitioners who after merely prescribing powders for children give them certificates of vaccination which will enable them to attend the public schools. Such lying and deceit merits only the condemnation and contempt of all lovers of science and truth.

Naturalists should also be on their guard against the influence of that new but rapidly growing sect, known as christian scientists, which virtually denies the existence of disease and accordingly, logically enough, disapproves of all teaching of physiology and hygiene. It has recently come within my own knowledge that a christian scientist refused to attend a lecture on domestic economy by an expert because the latter happened to be at the time attending a meeting of the American Public Health Association, alleging that no one could be worth hearing on the subject appointed who had anything to do with an association devoted to a purpose so useless.

With propagandists besieging more or less successfully our halls of legislation, the time has come when bodies like the American Society of Naturalists and the American Association for the Advancement of Science should have standing committees on legislation to take care, as far as possible, that unwise, extravagant or fanatical ideas regarding science and education shall not be given the force of law by the several States or by the Federal Congress.

If to-day we have little to fear from dogma or theology we may still have much to dread from foolish or needless legislation; and I desire to urge upon all those to whom these words may come, the duty, alike of individual watchfulness and of united effort, to resist everywhere and always the statutory subjection of science and education to propaganda.

## Clinical Report.

### ACUTE MORPHIN POISONING IN AN INFANT —RECOVERY.\*

CHARLES D. SLAGLE, M.D.  
CENTERVILLE, OHIO.

At 3 a. m., July 6, 1899, I delivered Mrs. W. of a well-formed and developed female child, weighing 8 pounds, after a normal labor in every respect. Recovery was slow and tedious, due to her highly neurotic temperament.

On the tenth day after labor, the patient suffered considerably from facial neuralgia, due to some carious teeth. This neuralgic trouble resisted ordinary treatment, so one-eighth grain of sulphate of morphin powders was given, with the instructions to the nurse, that a powder should be given every four hours until relief was experienced. This was done. About this time, the tenth day after the accouchement, the child developed considerable intestinal colic as the result of flatu-

lency, and a diarrhea set in. My attention was called to this and I gave  $\frac{1}{8}$ -grain Dover powder,  $\frac{1}{2}$ -grain bismuth subnitrate and  $\frac{1}{2}$ -grain soda bicarbonate, to be repeated every three hours till child was easier and diarrhea was somewhat controlled. This was successfully accomplished in a couple of days. From the end of the second week the mother's convalescence was more rapid and finally she was out of bed at the end of three weeks.

The child did well and increased in weight till the twenty-seventh day was reached, when the diarrhea set in again. The father called at my office on the evening of that day and asked if those diarrhea powders would answer which I had given some two weeks previous. He was told they would and was given instructions to give one every three hours till relief. At 11:30 p. m., August 2, I was hurriedly called to the bedside of the little patient by a messenger, stating that the child was dying. Upon arrival, the child was found to be suffering from poisoning from some cause. Inquiry elicited the fact that one of the  $\frac{1}{8}$ -grain morphin powders had been given the babe instead of the intestinal powders. The little patient was found in a comatose and narcotized state with considerable cyanosis. Pulse was 20, very irregular and weak. Respirations were 4 per minute and stertorous. Pupils were the size of a pin-point.

I gave at once 1/150 gr. strychnin sulphate and 1/300 gr. atropin sulphate hypodermically. Hot and cold affusions, alternating, were given by nurse, while the stomach was being washed out, first with strong infusion of black coffee, and finally with clear warm salt solution. High colonic lavage was practiced with the hot normal salt solution. The hot and cold affusions were soon changed to hot and cold baths, to keep up the respirations. As soon as these were stopped the child almost ceased breathing. At the end of one hour, the child was breathing somewhat more regularly. Pulse was 30, full and more regular. The above hypodermic was repeated, and hot and cold baths continued alternately. The action of the hot water was very stimulating to the heart, but if held in this bath too long the respirations became slower and almost ceased, when the cyanotic state developed again. At the appearance of the cyanosis the cold bath was substituted, and breathing again became more regular. This treatment was continuously kept up for five hours, when every half-hour a hot and cold bath was given for two hours. At the end of the seventh hour the respirations were 30 per minute, but not very regular. Pulse was 120, regular but weak. Pupils were moderately dilated. The child was yet sleeping profoundly and would not utter a sound, nor could be aroused. I gave 1/300 grain strychnin sulphate and 1/450 grain atropin sulphate, and in one hour pulse became stronger and respirations became more regular, about 40 per minute.

Here the little patient was placed in charge of the nurse with instructions to give another hot and cold bath should the child show any signs of dyspnea or the cyanosis appear again.

In about four hours the little patient was again seen and found to be sleeping; respirations 40, full and regular. Pulse was 140 and fairly good. At this time the child's temperature in the axilla was 99 F. No urination had occurred, nor had the bowels moved. The colon was again washed and some feces passed. The following was now given: tinctura belladonnae fol. gtt. ii, and tinctura nucis vomicae gtt. ii, every two hours till further instructed, with instructions in regard to the application of external heat. In about six hours the child was seen again, at 9 p. m., August 3, twenty-two hours after the ingestion of the morphin, and found to be resting comfortably. Respirations were 40; pulse was 120, full and regular. The child urinated at 8 p. m., a very small quantity. An attempt was now made to have it nurse the breast; the effort was successful. The convalescence was rapid and uninterrupted, and in four days the child was enjoying normal health.

No convulsions were seen in this case, as H. C. Wood, quoting Althaus, says: "In infants, however, and also in the lower races of mankind, as in negroes and Malays, convulsions are observed after its (opium) ingestion." No other effects or sequelæ were noted.

Some few years past the use of a solution of permanganate of potash was very frequently employed as a chemical antidote

\* Read before the Montgomery County, Ohio, Medical Society, April 5, 1901.

to morphin or opium. Some very unfavorable results occurred and to-day it is not so often used. Hence we must finally content ourselves in combating the narcosis of poisoning by morphin or opium by aiding the respirations and sustaining the circulation and eliminating the poisonous products from the system.

## The Organization of the Medical Profession.

(Continued from page 400.)

### VI.

#### THE REORGANIZATION OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association was organized fifty-five years ago, when there were about 20,000,000 inhabitants and possibly 25,000 physicians in this country. As organized the Association was a representative body, and its legislative and business affairs were controlled by delegates from affiliated societies,<sup>1</sup> such societies being entitled to one representative for every ten members. At that time this apportionment made a delegate body that was representative of the then existing societies, as well as of the settled parts of our country, and at the same time it was not larger than was necessary to transact business.

The rapid increase in population and the settling of vast territories were, of course, accompanied by a rapid increase in the number of physicians and also of medical societies. Naturally, the National Association grew in membership and its annual sessions gradually became larger and larger. In spite of this, however, no change in the apportionment of delegates was made during all these years, and until the last meeting of the Association every affiliated state, district and local society was still entitled to send one delegate for every ten members or fraction thereof. There finally developed such a condition of affairs that practically every member of the American Medical Association who desired to attend its annual sessions as a delegate could do so. This is to say, the numerous societies, and the low apportionment made it possible for all to be delegates who desired. Further, while the annual sessions through the increase in attendance and the excellent work of the sections were becoming more and more valuable from a scientific and educational point of view, the important legislative functions pertaining to a great body representing the interests of the medical profession of the country were neglected.

In the early history of the Association's existence, state societies were more in direct touch with it, since the delegates from these made up the greater portion of the delegate body. As time went on and other societies were organized, the representatives from and the influence of the state societies in the American Medical Association became proportionately less and less each year. In some instances a local society in a state being entitled to send more delegates than the state society itself. The natural result of these conditions has been that, in many instances, the original close relationship existing between the state and national association had become almost extinct, so much so that to many of the state societies the

American Medical Association was no more than any other large medical society. We refer those of our readers who desire a fuller understanding of the conditions prior to the reorganization last June to the full report of the Committee.

At the Atlantic City meeting, June, 1900, a Committee was appointed with instructions to consider and recommend a plan of reorganization. This Committee brought in a report at St. Paul, June, 1901,<sup>2</sup> which included a revised constitution to accord with the changes recommended by the Committee. The report and constitution were adopted. By this action two changes were made in the organic law of the American Medical Association.

The first of these provides for a reapportionment of delegates. As mentioned above, each affiliated society—state, district, county and local—was entitled to one delegate for each ten or major fraction of ten of its members. Under the new constitution the state societies alone will be represented, the lower societies being indirectly represented through their state organization. Each affiliated state and territorial society will be entitled to one delegate for each 500 or fraction thereof of its active members. All affiliated state and territorial societies, however, will be entitled to at least one representative, no matter how small the membership.

The second change gives the legislative body a distinctive name—the House of Delegates of the American Medical Association. While in one respect this might be called a new body, it is not strictly so. It is the old delegate body, but smaller, more representative and with a definite title. The old delegate body was unlimited as to number; in quite recent years the delegates numbered about 1500 last year over 1700 having registered. According to the new constitution the number of delegates is limited to 150. When it exceeds this number a new apportionment is to be made. Besides the representatives from the affiliated state and territorial societies, each of the twelve sections will have two representatives and the medical department of the Army, the Navy and of the Marine-Hospital Service one each. Hereafter, therefore, the legislative or business body of the American Medical Association will be created by the state and territorial societies, with the exception of the 27 from the sections and the Government Services. It will be a body in which the state societies will federate themselves, be national in character and will not be influenced by the locality in which the Association may happen to meet.

This evolution of the American Medical Association is the first step in a movement for a systematic organization of the profession of our country on a definite and distinctive plan. The beginning of the great movement had to be made at the top. But the American Medical Association has gone as far as it can and now calls on the state and territorial societies to do their part; successful organization now depends on the mutual co-operation of the state organizations with the American Medical Association.

#### WHAT THE AMERICAN MEDICAL ASSOCIATION ASKS OF THE STATE SOCIETIES.

The following resolutions, among others, recommended by the Committee on Reorganization were

1. At first certain colleges and hospitals were allowed to send delegates.

2. See JOURNAL A. M. A., May 25, 1901, p. 1435.

adopted at the last meeting of the American Medical Association:

c. That the state societies unitedly agree to federate themselves in the American Medical Association, and as a preliminary to this adopt a uniform organic law in regard to certain fundamental principles: viz., to divide their annual sessions into two branches, legislative and scientific; the legislative branch to be as small as is compatible with representation from all the county societies, and to be composed of delegates elected by the county societies.

d. That membership in the county or district societies shall constitute membership in the respective state society without further dues, and that no one be admitted to membership in the state society except through county or regular district societies.

e. That funds to meet the expenses of the state society be raised by a *per capita* assessment on the county and district societies.

f. That a united effort be made to influence special societies to limit their membership to those who support the regular organization, and the semi-national and miscellaneous societies to encourage systematic organization, by covering a definite territory and also by limiting their membership to supporters of the regular organization.

g. That each state society create a permanent committee and a fund for the purpose of enforcing all medical laws in every part of its territory.

h. That each state society co-operate with the American Medical Association and with the other state societies in solving the problems now before the profession relating to medical education, medical legislation, reciprocity, licensing, etc.

An analysis of these resolutions shows that the American Medical Association requests the following:

1. The federation of all the state associations in the American Medical Association.

2. That all associations adopt a uniform plan of organization as regards certain fundamental principles.

3. That each state association have two distinct branches, legislative and scientific.

4. That the legislative branch be as small as compatible with representation from all county societies in the state or territory, and to be composed of delegates elected by the county (or district) societies.

5. That the scientific branch be composed of and open to all members of county (or district) societies, or as stated in the resolution: "Membership in the county or district society shall constitute membership in the respective state societies without further dues, and that no one be admitted to membership in the state society except through county or regular district societies."

**Federation of the State Societies in the American Medical Association.**

In asking the various state societies to federate or unite in the American Medical Association, the latter is practically saying to them: "All of you join together, through representatives, and, thus united, be the American Medical Association. Each of you come, stating your needs and your views on the problems that affect the health of the people and the welfare of the profession. With your combined wisdom, consider what can be done to eradicate the evils from which the profession is suffering, both from within and from without, and how the science and art of medicine can be better applied in the interest of the health of the people."

In the future, by this federation, the legislative body of the American Medical Association will be what the state societies make it; and those who compose it will be the mouthpiece of those they represent, to give expression to their views and their desires. There is no doubt but that when the new conditions, with all their possibilities, are appreciated, the important questions brought before the House of Delegates will have been previously

considered and acted on by the legislative bodies of the state societies, and the representatives of such bodies will therefore bear a definite message on such important subjects to the national gathering. Thus will be developed and encouraged in the annual sessions of the state bodies a lively interest in affairs of national importance which relate to the health of the people and the welfare of the profession.

That there are many problems to be considered, evils to be eradicated, and conditions to be changed which can only be dealt with by the co-operation of all the state societies, has long been recognized. Uniformity in medical legislation, control and regulation of examinations for license to practice, interstate regulation of epidemics, etc., will be possible through combined action of organized state societies. One of the greatest evils afflicting our profession to-day, as it has been for years, is the large number of medical colleges of inferior grade. The evil is not due alone to the annual out-pouring of thousands of illy prepared men, with a lesser proportion, it may be, of those well-fitted for their work, but to the commercialism, the strife, the petty ambitions, jealousies and general demoralization which go with these, including free dispensaries, free clinics, and free hospitals. These, as well as the majority of the evils of which we complain, are brought on by ourselves, and can be corrected by our own efforts. But individual state organizations acting alone, no matter how strong they may be, can do but little. Well organized state societies combined together can purge the profession of most of the evils which originate in the profession. In the past there has been no possibility for co-operative work for general good among the state societies, and none has been attempted. In the future the state societies, through elected representatives, will be brought together in the House of Delegates for such coöperation. We may, therefore, look forward with hope for better things.

In brief, this federation is necessary as a bond of union between the state societies, to develop and cultivate the community of feeling that should exist in the profession throughout the country, to secure unity of action on national questions where the public health or the interests of the medical profession are involved, and to generally promote the scientific and material progress of American medicine. It is unnecessary to go into further details as regards this feature, the utility of which we take to be self-evident.

(To be continued.)

**Successful Laminectomy.**—G. Baarnhielm treated a case of spondylitis dorsalis and spinal paraplegia more than five months ago by laminectomy and the application of a plaster corset for a time. The patient was a tailor, 26 years old, who had previously had one testicle removed on account of local tuberculosis. The day after the evacuation of the abscess and caseous masses and extensive laminectomy, the patient was able to move both legs freely and made a rapid recovery. He is unable to work at his trade owing to slight kyphosis, but feels well and strong in another occupation and walks without support. The spondylitic paraplegia had existed for six months at the time of the intervention and the spondylitic process was at its height. The paraplegia was not quite total although spastic symptoms were very pronounced. No preliminary extension was attempted. Suspension and pressure on the hump aggravated the condition and instead of waiting for the tubercular process to reach the stage usually considered best for such intervention, Baarnhielm operated at once. It is the only case to his knowledge in which the paraplegia disappeared immediately after the intervention. Drainage was limited and brief.—*Nordiskt. Med. Arkiv.*, xxxiv, i, 3.

## LEGISLATION AGAINST DEGENERACY.

The idea of restricting the production of defectives is one that appears just at the present time to occupy a large place in the medical mind; hence the propositions sent out in medical papers or in resolutions of medical societies calling for legislation to prevent the marriage of the markedly unfit and to require a medical certificate as an essential preliminary for any license to marry. The multiplication of the defective and criminal classes has become so prominent a feature of modern civilization, and the public danger and expense they entail are so great that it is in no way astonishing that attention should be drawn to it and that radical measures for its prophylaxis be suggested. A hundred years ago society would have sought to make short work of the criminals and the other defectives would have been largely left to the tender mercies of the natural selective operations of mother Nature, which here would mean such neglect and maltreatment that they would not individually long continue a social problem. Moreover, the slower methods and lesser intensity of the struggle for existence did not make defective humanity so prominent a feature as do present conditions. Then sanitation was crude or almost unknown; the span of life was shorter for all and especially for the weaklings; there were no asylums to fill and the insane and idiot quickly went to ground or survived only as the town fools, whom many of even only middle age now living can recall. Crime flourished as ever, but there were no such great centers of population to concentrate it and few newspapers to make it prominent. They dealt with it more rudely then and almost every little county town had its occasional hanging show to which flocked all the countryside. The drunkard was common enough, but all drank and that made him almost respectable. There was not much sentimentality about the criminal in those days nor much more about the non-criminal who had the ill fortune to become a public charge.

Now we have changed all this; we congregate and care for our defectives and they consequently multiply on our hands, and we temporarily sequester our criminals and then turn them loose again upon the public. They are in modern eyes only unfortunates, and if it becomes necessary under laws which many declare relies of barbarism, to put them out of existence it must be in the easiest and most agreeable way. Further, in some respects, we have, in the course of our development, made

life harder; the nervous strain in the man of to-day is far greater than that endured by the man of sixty or one hundred years ago. Thus we make defectives by raising the normal standard. If the man of 1902 has not evolved sufficiently beyond the one of 1800 to meet the changes wrought in the past most progressive century of the world's history he is a defective. How many of our respected ancestors would fail to meet the modern conditions, no one can say, but it is likely that many who passed respectably in their day would succumb under the conditions of our modern strenuous life. Degeneracy is a comparative term and atavism may possibly be a serious matter even if it only "throws back" to a century ago.

Admitting that we save up and protect from ordinary and extraordinary perils our helpless defectives and that they therefore increase among us; that we coddle but hardly reform our delinquents; that the constantly increasing demands of modern life put the weaker ones more and more behind in the struggle for existence; that modern urban concentration with its intenser competition, its increased temptations and its less natural and healthy living tends constantly to deteriorate the type, and that all these work together, with still other not mentioned causes, to increase the output of degenerates, the question is, what are we going to do about it? Nature has her ways—rough ones they are—to mend matters, but we can not let her work unrestrictedly, not even as our forefathers did. The present answer to the question is apparently to have the reproduction of degenerates restricted by the methods suggested above. How effective these would be is a question, and it is another whether such rules carried to their logical sequence will really effect any good in their ultimate outcome. Restrictions on marriage for other reasons, economic or religious, have little effect in lessening the birth rate. There are countries where more than half of the births are out of wedlock, but the birth rate does not decrease. Who can suppose that restrictive laws would have prevented the notorious Jukes' family from multiplying? Surely nothing short of the strictest sexual segregation could have been effective.

The danger is that the legislation as proposed would only be restrictive on the most law abiding and would have little or no effect on the really degenerate. We might go so far as to possibly regulate marriage of the epileptic and perhaps some other pronounced defectives: such laws exist on the statute books of one or two states at least, but it is doubtful whether they are thoroughly enforced, and even the possibility of this is a question. When we come to take in the ex-insane, the neurotic and tuberculous, and all the others that are included as fit subjects for marriage restriction, the problem becomes practically an impossible one. Asexualization, which has been proposed by some, would be more effective, but we have not reached the social state where such procedures are likely to be legalized by law.

There is no need, however, of pessimism in regard to this matter; it will follow the rule and regulate itself in some way or other. It is perfectly legitimate to use educational methods, but unfortunately they are effective only with those who need them least. It would perhaps be better to encourage marriage rather than to restrict it. We can rely on one thing, viz., that the proletariat is always with us and will settle its own conduct in this respect, law or no law. If human stirpiculture is ever to be seriously considered, measures to increase the reproduction of the most fit will be far more natural and rational than those to put an extinguisher upon the most powerful and least controllable impulses that influence mankind.

#### PRACTICAL POINTS CONCERNING MALARIA.

In a recent number, notice was taken of the work of Celli and the Italians in emphasizing the economic side of malaria.<sup>1</sup> Another article has just appeared that deals with the practical side of malaria as seen in the tropical possessions of Germany in Africa.<sup>2</sup> Plehn takes it for granted that the plasmodium is the cause of malaria and that the disease is communicated to man by the bite of the mosquito. In his observations he recognizes the larger pigmented form of parasite with intermittent course, and a smaller form with sparse pigment corresponding in its morphology and clinical manifestations to the estivo-autumnal parasite. The value of blood examinations is not underestimated and the experienced physician can in this way not only tell the variety of malaria but can predict the time of the next paroxysm. Yet clinical manifestations generally enables one to make an accurate and positive diagnosis. Long-continued paroxysms of fever in the estivo-autumnal form speak for double or multiple infections.

There is only one curative agent, quinin. To employ any other, except perhaps, euquinin, is a waste of time. While possibly the "blackwater fever" is precipitated by quinin, Plehn is explicit in advocating quinin in all cases of malaria, warning against the possible occurrence of hematuria in much the same way that one warns against the possible development of nephritis after scarlet fever or neuritis after diphtheria. After recovery from malaria quinin should be given in weekly doses of fifteen grains, or better, in eight-grain doses every five days. This prevents relapse but does not confer immunity.

The negro inhabitants are practically immune. Yet Plehn finds, as did Koch, that the blood of negro children often contains the parasite, and the children, if they are carefully watched, will be found to have splenic enlargement and slight fever, i. e., mild manifestations of malaria. They are by this mild attack rendered immune against future attacks, as they are born relatively im-

mune because of hereditarily transmitted tendencies. Europeans, however, lacking any hereditary immunity or any that is acquired through mild malaria in infancy, readily fall victims to the severe forms of the disease. The comparison is very aptly made between the behavior of the black toward malaria and the white toward measles. It is well known that when communities where this latter disease has not appeared are infected with measles, old and young alike are stricken with a most severe and malignant type of the disease. Through centuries of contact with measles the white man is relatively immune. Plehn suggests that immunity against paludism might possibly be artificially conferred by purposely inoculating individuals by means of the bites of infected mosquitoes and permitting only a mild form of malarial fever to develop by giving small doses of quinin. Experiments along this line are justifiable.

Prophylaxis by means of screening windows, wearing clothing that protects the body from the bites of insects, remaining indoors after sundown and keeping away from districts known to be infected, should be rigidly advised and if necessary enforced by law on sailors and Europeans. One may judge of the susceptibility of the European to malaria by reading Plehn's statement that if 100 Europeans were to attempt to acquire immunity, permitting themselves to be inoculated by the bites of infected mosquitoes and if they were not to take quinin, out of this 100 at least 90 would die, and 9 would be left in a wretched condition of weakness and debility, while one, perhaps, would pass through the ordeal unharmed.

From the experience of this observer, who, while thoroughly scientific, does not overlook the practical side of the question, one sees how important is the attention to the details of prophylaxis, how dependence is still upon quinin, how important from an economic point of view the doing away with this scourge of the tropics and how there are still many problems of scientific interest that still remain to be solved and whose solution will be of immense value. A vaccination against malaria is the great desideratum of the tropical world.

#### THE EFFECT OF GASTRIC JUICE UPON TUBERCLE BACILLI.

Apropos of the recent vigorous discussions regarding the possibilities of infection of the human organism by the bacillus of bovine tuberculosis the question of the effect of the gastric juice upon the tubercle bacillus becomes of particular interest. It is admitted that if man is infected by bacilli from cattle the infection is generally alimentary, from foodstuffs, rather than respiratory as in human contagion, and hence infecting organisms must be subjected to the antiseptic digestive fluids for at least some time. As early as 1883 this subject was considered, first by Falk, who found that caseous materials exposed for some time to the action of an artificial gastric juice were still capable of infecting guinea-pigs. Wesener found that tuberculous sputum mixed with artificial gastric juice and injected into the cecum of a rabbit

1. JOURNAL A. M. A., 1901, July 20, p. 201.

2. F. Plehn: Ueber die praktischen Ergebnisse neueren Malariaforschung und einige weitere Aufgaben derselben. Deut. Med. Woch., 1901, Nos. 46, 48, 49.

produced tuberculosis at that point. Straus and Wurz found that prolonged action of artificial gastric juice upon avian tubercle bacilli attenuated them somewhat, sometimes killing them, but stated, however, that the conditions of the experiment were more severe than those presented during life. Nevertheless, despite the qualifications made by Straus and Wurz, their work has been widely quoted, according to Carrière,<sup>1</sup> as showing that gastric juice kills the bacillus of tuberculosis.

On account of the unnatural conditions under which these experiments were performed, Carrière thought to repeat them in a way more nearly duplicating natural conditions. One series was performed with gastric juice obtained from the stomach of a healthy man. Tubercle bacilli, in sputum, milk and pure culture, were exposed at body temperature to the action of this juice from two to twenty-four hours. It was found that twelve hours exposure, more than they would suffer in the human stomach in the natural course of events, had no effect upon their virulence. Another series of experiments, even more nearly reproducing natural processes, consisted in introducing the tuberculous materials into the stomachs of healthy guinea-pigs and rabbits, and after it had remained there for variable lengths of time it was removed and injected into other animals, which it infected invariably. Evidently, then, gastric juice does not offer much safeguard to infection from tuberculous food. Agreeing with its general behavior to injurious influences the bacillus of Koch resists hydrochloric acid more than most other organisms. For example, Schultzenstein<sup>2</sup> finds that the cholera spirillum is killed in fifteen minutes by a solution of .03 per cent. hydrochloric acid. Although gastric juice does not destroy tubercle bacilli quickly, still it apparently is able to prevent their multiplication, for a tuberculous ulcer in the stomach is one of the greatest rarities. Simmonds<sup>3</sup> found that they existed but eight times in the bodies of two thousand tuberculous subjects, and even then seemed dependent upon digestive disorders.

The experimental observations above referred to have been made on human and avian bacilli. Because of the bearing on food infection it would be interesting to learn if bovine bacilli are equally resistant to human gastric juice.

#### THE ONE THING NEEDED BY THE HOMEOPATHIC SCHOOL OF MEDICINE.

In the Jubilee Number of the *North American Journal of Homeopathy* (1, 1902, 54), Dr. Millsop gives a gloomy view of the present state of homeopathic therapeutics. A bright picture is first exhibited, depicting the satisfactory side of the situation. The author says: "We have surgeons galore of the best quality; fine college buildings equipped with every modern appliance and competent instructors, numerous hospitals, dispensaries, etc., with a larger percentage of cures than recorded by

any other school of medicine. In diagnosis we call to our aid all known scientific methods." After this array of the possessions of the "school," there follows a very pathetic narration of the one thing which it does not have, and which has always been supposed to be the one thing that distinguished the homeopathic from other "schools" of medicine and from scientific medicine. "There is one thing needful to render us the successful practitioners we could and should be. This one essential is a more thorough knowledge of our materia medica, and a more intelligent application of our remedies in practice. This need has been impressed upon me more especially during the past seven months, while upon an extended trip through the South and West. Everywhere the complaint was made by physicians and successful surgeons of our school that there are so few good prescribers and that many of our doctors are resorting to every other means of cure rather than to the prescribing of their own remedies. So general has this state of things become that the sad conclusion has been well-nigh forced upon me that homeopathic remedies are going out of fashion."

If the remarkable success of homeopathic institutions related by the author is due to the therapeutic skill of doctors who are resorting to every other means of cure rather than to the prescribing of their own remedies, it is poor logic which credits homeopathic treatment with the results. It does not appear to have occurred to the writer that the well-equipped colleges with competent instructors in other departments than therapeutics may have been a factor in inducing men, who thus obtain some scientific training, to adopt any means of cure which reasonably promises to be of benefit to the sick, even though it may not consist in the administration of infinitesimal doses. It is a favorable sign to find a faithful disciple of Hahnemann who acknowledges the natural tendency of which most medical men are aware, and it causes us to renew our hope that the time is not so very distant when the believers in the efficacy of dilutions will cease to shut themselves up in a "school" and will become a part of the regular medical profession, the members of which are ready and anxious to employ any and every means which can be scientifically shown to have a favorable influence upon the course of disease.

#### FARM COLONIES AND TENT LIFE FOR THE TUBERCULOUS.

A great deal has recently been said and written about sanatoria for tuberculous persons, and regarding the value of open air and light in the treatment of such patients. Freudenthal<sup>1</sup> advocates what appear to be practical means, by which many tuberculous patients might be placed in very favorable conditions upon "farming colonies." The colony would be established upon a large farm, which has a favorable location as to climate. The buildings could be inexpensive, and a large part of the year could be spent in tents, which mode of life is

1. New York Medical Journal, lxxv, 1902, p. 146.

beneficial in itself. Norman Bridge<sup>2</sup> called attention in our pages to the fact that most of the climatic benefit that comes to this pathetic class of patients is due to their ability to live practically out of doors a large part of the time, night and day. The patients could help to place such an institution upon an economic basis by doing such light work as they were able to perform, and this would be beneficial to them, both physically and mentally. Such a plan if carried out would place tuberculous patients with small means in a position to obtain the advantages of climate and out of door life which at present can only be gotten with considerable expense, and in many cases is absolutely out of the question. By a certain amount of State aid, persons unable to pay could be provided for upon such a plan at no greater cost than is now required to care for them in poorly located, unsuitable, and often crowded hospitals.

#### A SELF-SACRIFICING PHYSICIAN.

What is the matter with Brooklyn? Within a few weeks one local practitioner of that borough has come into prominence by his alleged experiment of inoculation of a woman with tuberculosis, and now another proposes to go him one better by submitting his own body for a year to vivisection. Of course, it is for the highest kind of scientific considerations that these heroic men sacrifice others and themselves: all the world knows that, and if any doubt existed as to this point it would be dispelled by their own persistent and strenuous efforts to inform the public through the press as to the scientific purity of their motive. They are always "leading physicians"—the newspapers say so, possibly on the highest authority, that of the parties themselves. With such evidence available the unsequential fact that we have never heard of them before goes for nothing, and we can appreciate the pain they feel from the newspaper notoriety they obtain and the ignorant and unfeeling comments their projects receive. It is said that in this latest case the wife's urgent entreaties have called the doctor off from his proposed self-sacrifice, thus showing a limit to his scientific enthusiasm. He evidently does not go so far as Artemas Ward; there is one of his wife's relations—by marriage—that he is willing to spare. A daily paper rather unkindly suggests that the heroism exhibited by the volunteer for vivisection hardly matches that of the vivisectors, should he discover them, who might have to undergo equally or still more unpleasant operations at the unskilled hands of unscientific officers of the law. It is to be suspected that this kind of heroism will be found lacking. It would require a degree of immoral courage that is rarely at command in the medical profession.

#### A WISE CORONER'S JURY AND EDDYISM.

In Michigan recently, a Wayne County coroner's jury returned the following verdict in the case of a believer in Eddyism who died without medical attendance:

We find the deceased came to his death as a result of a complication of diseases, mostly acute in form and character, and that his end was untimely and most miserable, owing to his being denied the medical supervision and treatment which by the common consensus of the best opinions of the most enlight-

ened of mankind and the accumulated experience of all time has demonstrated to be necessary and imperative in the proper prevention of disease and death, and the humane amelioration of human suffering. We find inhuman treatment accorded said deceased was by a so-called sect of "christian scientists" in disregard of all basic and physiological laws.

We have more than once had occasion to criticise the decisions of coroner's juries and it is therefore a positive pleasure to quote one that deserves only commendation as in this case. There were, it is said, some peculiar features in this case: among them an internal abscess, of course undiagnosed, but the physicians who made the postmortem saw nothing that would have prevented recovery under proper medical or surgical treatment. "Absent" treatment by an Eddyite practitioner was sought for but was claimed to have been ineffective because he could not read correctly the name as sent to him, thus showing one of the limitations of Eddyism; the little god of the Eddyites can do nothing with bad writing. As the *Detroit Free Press* says in editorially noticing the case, from one point of view the subject is too ridiculous to be seriously discussed. In another, however, it shows a serious condition of affairs; owing to the laxity of our law-makers and law-administrators and the general public delusional apathy this kind of manslaughter, to use no harsher term, can be committed with impunity and only rarely does it receive such a wholesome condemnation by any legal authority. The Michigan jury, however, did its duty and we are glad to have the opportunity to notice the fact.

#### DIABETES FROM INJECTION OF ADRENALIN.

The suprarenal gland has long been an organ full of mystery. The preparation of the active substance or substances of this gland known as adrenalin (Takamine) is endowed with powerful properties. Recently Herter and Richards<sup>1</sup> showed that the injections into the abdominal cavity of dogs of adrenalin solution, 1 in 1000, in doses of from 6 to 10 c.c., in each instance produces well-marked glycosuria. In one instance the sugar appeared in the urine in less than five minutes after the injection. Blum, Luelzer and Croftan all found that the suprarenal gland had some influence upon carbohydrate metabolism. Croftan<sup>2</sup> concluded that the glycosuria observed by him depended upon a ferment in the suprarenal gland which changes the glycogen of the liver into sugar. But Herter and Richards show that boiling the adrenalin solution for five minutes, which would be expected to destroy any diastatic ferment, does not suspend glycosuria after experimental injection. Furthermore, glycogen and adrenalin added together and kept in the incubator do not result in the production of sugar. Hence these authors do not refer adrenalin glycosuria to a diastatic ferment. In some of their experiments they found marked changes in the intestines and pancreas. In two dogs that died after the injection of 6 c.c. of adrenalin (1 in 1000) the cells of the islands of Langerhans of the pancreas were granular and degenerated, the nuclei refusing to stain; and in some parts of the pancreas the islands of Langerhans were more

1. Medical News, Feb. 1, 1902, 201-203; see also abstract in this issue, p. 478.

2. American Medicine, Jan. 18, 1902; see also THE JOURNAL A. M. A., editorial comment, p. 402, Feb. 8, 1902.

injured than the adjacent cells of the pancreatic acini. They mention an experiment in which 1 c.c. of adrenalin solution (1 in 1000) plus 1 c.c. of water applied to the surface of the pancreas gave rise to an immediate blanching followed by congestion, and within ten minutes by the appearance of sugar in the urine. These interesting experiments naturally awaken the disposition to further inquiry. Coming so closely upon the demonstration by Opie, Herzog and others, that in diabetes the islands of Langerhans may be the seat of profound changes, the results of these experiments can not but strengthen the notion that some cases at least of diabetes are dependent upon lesions in these bodies, but the exact and no doubt very complicated mechanism whereby the resulting diabetes is produced still remains to be worked out.

## Medical News.

### CALIFORNIA.

**Smallpox** is reported at Arbutle, where there are five cases and at Sierra City where two cases exist.

**Mare Island Quarantined.**—The naval hospital at Mare Island is in quarantine, on account of smallpox.

**Illegal Practice.**—Robert Macbeth, San Francisco, charged with practicing medicine without a certificate, was convicted January 30.—N. C. Heron, a patent medicine manufacturer who signed a death certificate, was arraigned at Los Angeles, fined \$150 for practicing without a certificate and paid his fine.

**Status of Local Health Boards.**—The Supreme Court has decided that the municipal board is a legally constituted body and has jurisdiction over the local health of the city and county, and it also intimates that the state board has other powers, partly independent and partly paramount to those of the local board.

**Hospital for Indigent Consumptives.**—Plans are being prepared for the first of the series of one-story buildings at Los Angeles designed for the care of indigent consumptives. Each building will contain six wards, bath room, dispensary and nurses' rooms. An administration building is to be erected at the same time, and additional hospital buildings as required.

### DISTRICT OF COLUMBIA.

**Scarlet fever** of mild type is prevalent in Tacoma Park, where 14 cases have been reported.

**Antivivisection Bill.**—Mr. Gallinger has introduced in Congress the old bill "to prevent cruelty to animals"; it is now labeled "S. 3068."

**Hospital Board Election.**—At the annual meeting of the medical board of Providence Hospital, Dr. John W. Bayne was elected president, Dr. Zachariah T. Sowers, vice-president, and Dr. Thomas F. Mallan, secretary.

**Personal.**—Dr. J. Ramsay Nevitt, Washington, who has been ill with appendicitis, is improving.—Dr. Presley M. Rixey has been appointed a member of the board of directors of the Columbia Hospital for Women, vice Dr. Louis W. Ritchie, deceased.

### GEORGIA.

**Medical Legislation in Georgia.**—Bills are being prepared under the direction of physicians for introduction into the Georgia Legislature, covering the following points: All coroners are to be practicing physicians; all proprietary medicines brought into the state must be labeled so that the public can know the ingredients and the proportion of each ingredient; no poisonous drug or narcotic, such as morphin, etc., shall be sold without a physician's prescription.—*Southern Med. Journal.*

### ILLINOIS.

**Pontiac Hospital.**—The citizens of Pontiac have subscribed \$10,000 toward the erection of a hospital in that city.

**Smallpox.**—Woodhull, Henry County, is experiencing the usual sequelae of diseases diagnosed as chicken-pox, Cuban itch, pustular grip and Porto Rican pox, and now has about 75 cases of smallpox.

**Evanston's Health.**—The report of the health officer for 1901 shows a death-rate of only 8.65 per 1000, the lowest

mortality since 1896. Tuberculosis heads the list of death-causes, with heart disease next and pneumonia third.

**Rockford Hospital Enriched.**—Alexander D. Forbes has presented \$15,000 to the City Hospital, to be used in the erection and furnishing of a new ward for young women and children. He does this in memory of his daughter, Jessie Elizabeth Forbes, by whose name the new department will be designated.—The Rockford Chapter of the Daughters of the American Revolution has given \$1000, a prize received from an eastern magazine, to the hospital.

### Chicago.

**Dr. Alice M. Steeves** has resigned her position in the oral surgery clinic of the Woman's Medical College and will remove to Boston.

**County Hospital Staff.**—At the annual meeting of the regular staff of Cook County Hospital, February 6, Dr. Arthur R. Edwards was elected president and Dr. L. Blake Baldwin, secretary.

**Dr. E. C. Dudley**, in compliance with the wishes of the trustees of Northwestern University and of the faculty of Northwestern University Medical School, has withdrawn his resignation and has resumed his duties at the school.

**Influenza Epidemic.**—There is noted a general increase in the prevalence of all the contagious diseases—influenza, diphtheria, scarlet fever, whooping cough, etc. Influenza prevails as an actual epidemic and the Health Department predicts that the mortality from pneumonia, Bright's disease and heart diseases will be most unfavorably affected as a consequence.

**New Amphitheater Dedicated.**—The new amphitheater built in Mercy Hospital at the expense of the Northwestern University Medical School (Chicago Medical College), at a cost of \$25,000, bringing into closer relations the affiliation between Mercy Hospital and the medical school, was opened with appropriate exercises, February 12. Dr. John B. Deaver, Philadelphia, delivered the address. He gave a surgical clinic in the amphitheater on the morning of the same day.

**The City's Mortality.**—The 530 deaths from all causes recorded during the week made an increase of 2.5 per cent. in the mortality rate over the rate of the previous week and of 10.3 per cent. over the rate of the corresponding week of 1901 in proportion to population. The respective annual death rates per 1000 were 15.18, 14.80 and 13.76. Among the principal causes of death pneumonia, diphtheria and scarlet fever show the greatest increase.

**Chicago's Immunity from Smallpox.**—The wonderful immunity of Chicago from the disease continues. During the week twenty-eight "suspect" cases were examined by the medical inspectors, but only four were found to be genuine cases. Of these, three came by rail—one from Mexico, one from Elkhorn, Wis., one from Calvary, Wis., and one by boat from Milwaukee. None had even been vaccinated. No Chicago case developed during the week and at midnight, February 8, there were 18 cases in the isolation hospital.

### INDIANA.

**Methodist Hospital.**—Indiana Methodists have undertaken to raise \$200,000 for the erection, and \$500,000 for the endowment, of a hospital at Indianapolis.

**Hospital for Huntington.**—The business men and railway employes of Huntington have subscribed \$2000 toward a public hospital for the city. A site has already been secured.

**Union Hospital, Crawfordsville.**—Mrs. Culver, St. Louis, who originally donated \$10,000 to the hospital, has given an additional \$3000, to be devoted to interior finishing and furnishing.

**Losses by Fire.**—Dr. Frank S. Kitson, North Manchester, sustained a loss of \$2000 by the burning of his home, January 29.—The house of Dr. Zeri H. Fodrea, Westfield, was burned, January 28, with a loss of \$2000.

**Crown Point Sanatorium.**—The new sanatorium was opened, January 15. It is a four-story brick building, with modern fittings and equipment, and has a competent medical staff consisting of Drs. William B. Blackstone, George D. Brannon, Henry Pettibone and Joseph Von Osinski, of Crown Point, with Drs. Emil Ries and D'Orsay Hecht, Chicago, as consultants.

### IOWA.

**Hospital Burned.**—The hospital conducted by the Sisters of Charity at Anamosa, was almost ruined by fire, January 30. All the patients were removed uninjured.

**To Replace Medical Building.**—The chairman of the appropriation committee has recommended an appropriation of \$250,000 to replace the medical building which was recently burned.

**Hospital for McGregor.**—Dr. Henry H. Clark, McGregor, is building a hospital, to cost \$18,000, which will be ready for occupancy early in April. It contains 35 rooms and will be fully equipped.

**Quarantine Breaker Fined.**—Dr. Samuel C. Kirby, the Grand Junction physician who was charged with breaking smallpox quarantine last summer, was recently fined \$250 and costs which will aggregate \$400.

**Smallpox.**—The State Board of Health on February 8, adopted the following preamble and resolution:

WHEREAS, Cases of smallpox exist in nearly every county in this state; and,

WHEREAS, Smallpox has occurred in the family or person of some of the postmasters of the state; therefore,

Resolved, By the State Board of Health of the state of Iowa, that the postmaster-general be requested to require so far as possible all postmasters in Iowa and their employees, including city and rural carriers with their families, to be vaccinated, and to furnish to the local boards of their respective localities satisfactory evidence of successful vaccination.

#### MARYLAND.

**Malignant erysipelas** is said to be prevailing among the negroes of Marlboro, Prince George County.

**Baltimore Mortality.**—The deaths for the week ending February 8 were only 187, against 271 for the same week in 1901. The chief cause of death was pneumonia, 27 cases.

**Vaccination of Baltimore-Bound Crews.**—Surgeon-General Wyman, of the Marine-Hospital Service, has acceded to the request of the Health Commissioners of Baltimore, and has telegraphed to Liverpool that the crews of all vessels sailing for this port must be vaccinated. He says that any ship will now be held up whose crew can not show that they have been vaccinated.

**Personal.**—Dr. J. Williams Lord, secretary of the Medical and Chirurgical Faculty of Maryland, has sailed for Cuba.—Dr. Henry W. McComas has purchased a residence on Main street in Oakland, and will establish there a sanatorium.—Dr. Henry Cozens, Hagerstown, was appointed dairy inspector of Washington County.—Dr. T. W. Simmons, Hagerstown, was acquitted, February 1, of the charge of violating the health laws by failing to report an alleged case of diphtheria last summer. The warrant was sworn out by the county and state health officers.

#### MICHIGAN.

**The Detroit Polyclinic** held its annual meeting, January 27. The report shows that 2700 patients were treated during the year. The following officers were elected: Dr. James E. Davis, president; Dr. Louis J. Goux, vice-president; Dr. S. G. McDonald, secretary, and Dr. F. E. Sanderson, treasurer.

**Disease in Michigan.**—Reports to the State Board of Health indicate that bronchitis, influenza, rheumatism, neuralgia and tonsillitis, in the order named, caused the most sickness during the week ended February 1. Cerebrospinal meningitis was reported present at 4 places; whooping cough, 27; diphtheria, 27; typhoid fever, 48; measles, 60; scarlet fever, 117; smallpox, 139; and consumption at 215.

**Smallpox.**—Norway is said to have more than 100 cases, and public assemblages are prohibited until the epidemic is over.—A train was recently held at Grayling for three hours while all the passengers were vaccinated on account of a case of smallpox having been discovered on board.—In Wyandotte and Ecorse township, the schools have been closed, as 32 cases of the disease exist.—The asylum at Traverse City has 6 cases in mild form.

**Michigan's Deaths.**—The number of deaths from all causes in Michigan during 1901 was 33,848, as compared with 33,320 during 1900. The annual death-rate was 14 per 1000. The deaths of children up to 4 years of age showed a decrease as compared with the previous year. On the other hand, the proportion of deaths of persons aged 65 years and over rose from 8754, or 27.5 per cent., to 9524, or 29.5 per cent. Pneumonia, both in 1900 and in 1901, was the most fatal disease. There were 2759 deaths reported directly or indirectly from this cause in 1900 and 2993 in 1901.

**How Long!**—A Dowagiac paper, at this late date, thus notices the advent of a strange disease: "The doctors are badly puzzled over a disease which has manifested itself here, and no two of them seem to agree as to what to name it. It has been

raging here six or eight weeks. Smallpox, Cuban itch, Dakota itch and la grippe are the various names that have been attached to it. The disease, whatever it is, is not a violent one, and leaves the person afflicted within a few days, and sometimes even without the care of a physician. No one appeared to be much frightened over it until last Sunday the health officer closed two of the public schools and quarantined and placarded several homes 'smallpox.'"

#### NEW HAMPSHIRE.

**Personal.**—Dr. Orlando B. Douglas has moved from Suncook to Concord.—Dr. James Black has located in Nashua.—Dr. Irving A. Watson, Concord, secretary of the State Board of Health, fell and broke his leg.

**Hospital Bequests.**—By the will of Mrs. Emeline R. Balch, Manchester, Elliot Hospital receives \$3000, and after the payment of bequests the balance is to be devoted to the establishment and maintenance of a hospital in Manchester to be known as the Balch Hospital.

**Elliot Hospital, Manchester.**—At the annual meeting, January 14, the following medical staff was appointed: Attending physicians and surgeons, Drs. George D. Towne, J. Franklin Robinson, L. Melville French, William H. Pattee, A. Gale Straw, Daniel S. Adams, Charles F. Flanders, and John H. Gleason; aural and ophthalmic physicians, Drs. Henry DeW. Carville and Emdon Fritz; assistant surgeons and physicians, Drs. Irving L. Carpenter, George M. Watson, Thomas C. Hill and F. C. Stewart.

#### NEW YORK.

**Incipient Tuberculosis Hospital.**—The senate has passed Senator Davis' bill, appropriating \$50,000 for a state hospital for treatment of incipient tuberculosis.

**Hospital Endowed.**—It has just become known that, a short time prior to the death of William F. Cochran, Yonkers, he established a fund of \$150,000 for the endowment of St. John's Riverside Hospital at that place.

**Marine-Hospital for Buffalo.**—A bill appropriating \$125,000 for a marine-hospital to be erected at this port has been favorably acted upon by the committee on interstate and foreign commerce of the House of Representatives.

**The Rodgers bill**, embodying Governor Odell's views for the control of the state charitable institutions, and abolishing local boards of managers for state hospitals for the insane, finally passed the senate by a vote of 31 to 18. It was vigorously opposed, and by many who are in a position to judge, this is said to be a distinct step backward.

**Emergency Hospital for Bronx Borough.**—Senate bill No. 250, introduced by Mr. Hennessy, authorizes the Sinking Fund Commissioners to acquire land for the erection thereon of a reception hospital for persons injured or taken ill suddenly in the Borough of the Bronx. Entire cost of land shall not exceed \$200,000, and the cost of the building and equipment and furnishing shall not exceed \$300,000.

**Evolution of Consolidation.**—The council of the New York State Medical Association has acted promptly on the resolution of the Medical Society of the State of New York and has appointed a committee to confer with a like committee from the Society, with a view to a union. The committee appointed by the New York State Medical Association consists of Drs. E. Eliot Harris, Parker Syms, Emil Mayer, W. H. Biggam, and Frederick Holme Wiggins.

**New York Deaths.**—In addition to the 129,257 deaths for the year reported in the monthly bulletin of the State Board of Health, there were 1500 delayed returns, making the annual death rate 18 per 1000. The mortality was 7500 in excess of the average of the past five years, but the rate was the same as that of 1900. The sanitary districts all participate in the variations of mortality. The infant mortality is unusually low, being 3500 less in 1900 and 2500 less than the average of the past five years.

**Decrease in Tuberculosis Deaths Among Prisoners.**—The Superintendent of State Prisons, in his annual report, calls attention to the great decrease in the prevalence of tuberculosis among the inmates of the prisons as a result of transferring all convicts suffering from this disease to Clinton Prison, in Clinton County. Statistics which have been prepared by Dr. Julius B. Ransom, the physician of Clinton Prison, show that from 1891 to 1895 there were 253 deaths among the prison population of the state, whereas from 1896 to 1900 there were only 72, a decrease of 71 per cent.

### New York City.

**Increase of Smallpox.**—Smallpox is admitted by the health authorities to be on the increase. One of the students attending the University Medical College was found to be broken out with smallpox. He was hurried to North Brother Island, and vaccination on a large scale was instituted.

**Mount Sinai Hospital.**—The annual meeting of the hospital was held January 26. The expenses for 1901 were \$119,234, and 3196 patients were treated, 2386 of whom were free patients. There has already been subscribed for the building fund \$1,294,281 of the \$1,650,000 required. The gifts for the year amounted to \$45,045, of which \$38,000 was given by individuals not of the Hebrew faith.

**Reforms in the Barber Shop.**—The new Commissioner of Health, Dr. Lederle, has announced his determination to institute certain reforms in barber shops. The prohibition of the use of a sponge on the face after shaving, of the use of the powder puff, of the use of alum in stick form, and of the use of a towel more than once are among the proposed changes. The new regulations are to be posted conspicuously in every barber shop, and the customers are relied upon to see that they are enforced.

**Personal.**—Dr. Charles G. Child, Jr., has been appointed assistant visiting gynecologist to the City (charity) Hospital. —Dr. Warren S. Simmons has been appointed to the regular staff, Dr. William B. Brinsmade promoted to visiting surgeon, and Dr. George G. Hopkins made consulting surgeon at St. John's Hospital, Brooklyn. —Dr. George W. Salter, an eclectic physician of Brooklyn, was fined \$50 for not reporting a case of smallpox. He first diagnosed the case as one of diphtheria, but when convinced that it was smallpox neglected to notify the health authorities. —Dr. William V. Paschal, who was house surgeon at St. Mary's Hospital, Brooklyn, and who by prompt operation saved the life of Robert J. MacFarland's son, has been gratefully remembered by Mr. MacFarland. A dinner was given in honor of the physician, and he was presented with a gold watch valued at \$1000. —Dr. Louis W. Schultze, who was general medical inspector for the Department of Charities under the last administration, at a salary of \$3000, has been removed by the new commissioner, Homer Folks.

**Protest Against Exclusion of Tuberculous Aliens.**—The Academy of Medicine, at its meeting, February 7, adopted the following resolutions:

WHEREAS, The Treasury Department of the United States, upon recommendation of the Surgeon-General of the Marine-Hospital Service, has recently decided to classify pulmonary tuberculosis with dangerous contagious diseases, be it

*Resolved*, That the New York Academy of Medicine deeply deplores this decision, which is not based either on clinical experience or on scientific experiments.

*Resolved*, That the Academy considers the exclusion of non-pauper tuberculous immigrants and consumptive aliens visiting our shores unwise, inhumane, and contrary to the dictates of justice.

*Be it further resolved*, That, while the Academy is convinced of the communicability of tuberculosis and urges all possible precautions against the spread of the disease occasioned by sputum and tuberculous food, the Academy is opposed to all measures by which needless hardship is imposed upon the consumptive individual, his family, and his physician.

**Post-Graduate Needs.**—Dr. John A. Wyeth has sent a letter to the daily press, setting forth to the public the needs of the post-graduate medical schools in this city, and the good work done by them. He said that wealthy and generous people had been slow to appreciate what post-graduate medical instruction meant to the state. While it was admitted that the best training in practical work for the young graduate in medicine was obtainable by serving as an interne in a hospital, not more than ten in a hundred could avail themselves of these privileges. The remaining nine-tenths must obtain their practical training by post-graduate instruction, and the need for carrying on such work in small classes and with the aid of costly laboratories made it impossible for these schools to be self-sustaining. Dr. Wyeth said that these schools deserved financial aid, not only because they attract annually from one to two thousand practitioners of medicine from all parts of the globe to New York, but for the one great reason that they are teaching physicians in practice to administer more scientifically and successfully to the sick and injured throughout the land.

### PENNSYLVANIA.

**Typhoid fever** is still prevalent in Pittsburg, the 22 cases reported in a single day being located in 10 different wards.

**Appropriation for Hospital.**—The council of Allegheny has made an appropriation of \$10,000 to the Allegheny General Hospital.

**Smallpox Hospital Burns.**—The Washington County isolation hospital at Scenery Hill has been destroyed by fire. The fire is said to have been incendiary. One patient succumbed to the exposure and excitement, and others are in serious condition.

**St. Joseph's Hospital, Lancaster,** at its annual meeting, appointed the following staff: Visiting surgeons, Drs. Herbert R. Bowers, Samuel T. Davis, Newton E. Bitzer and Edmund B. Ilyus; visiting physicians, Drs. George P. King, Henry E. Muhlenberg, Oliver Roland and Samuel W. Miller; consulting surgeon, Dr. George R. Welch; consulting physicians, Drs. John H. Grove, Philadelphia, Ambrose J. Herr and Robert M. Bolenius.

**Personal.**—Dr. Orion S. Rhodes has moved from East Stroudsburg, to Laramie, Wyo. —Dr. Walter D. Diefenderfer, York, has been appointed deputy medical inspector to the State Board of Health, for the Pennsylvania Railroad. —Dr. Walter Lathrop has been re-elected superintendent of the Hazleton State Hospital. —Dr. John L. Atlee has located in Lancaster. —Dr. George F. Wise, Tyrone, has gone to Philadelphia as clinical assistant to Dr. L. Webster Fox. —Dr. Emmett A. Sprowls, West Alexander, has moved to Keokuk, Iowa. —Dr. Thomas B. Echard, Connellsville, has won a position on the resident staff of the Pennsylvania Hospital, Philadelphia. —Dr. R. C. Craig, U. S. M.-H. Service, is to remain in Pittsburgh as assistant to Dr. F. W. Meade, who has been ordered to that post from New Haven, Conn.

### CANADA.

**Personal.**—Dr. J. F. W. Ross, Toronto, will spend the next two months at Nassau in the Bahamas.

**New Laboratory at Hamilton.**—The medical health officer, Dr. Langrill of Hamilton, is urging the Board of Health of that city to equip a laboratory which is especially needed for diphtheric cases. He points out that in 1901 in that city 25 per cent. of the cases proved fatal. A new Isolation Hospital is to be built.

**American Medico-Psychological Association.**—The fifty-eighth annual meeting of this Association will be held in Montreal June 17, 18, 19 and 20, with headquarters at the Windsor Hotel. Dr. Wyatt Johnston will deliver the annual address on the subject of "The Medico-Legal Appreciation of Trauma in its Relations to Abnormal Mental Conditions."

**Tuberculin Test.**—The annual meeting of the Canadian Shorthorn Breeders was held in Toronto on January 4, when a special committee on the tuberculin test reported as follows: "We, the members of the Dominion Shorthorn Breeders' Association at our annual meeting resolve that the tuberculin test is unreliable, unnecessary and in many ways injurious, and that we urge the discontinuance of the compulsory use of it by the Dominion Government Department of Agriculture."

**Consulting Health Board Proposed for Montreal.**—Alderman Ames, who has always taken a deep interest in all matters pertaining to the health of Montreal, is trying to have a consulting board appointed to work with the Hygienic Committee of that city. This Board is to consist of four physicians, two English and two French, and a practical plumber. A war will be at once started on privy pits as Alderman Ames has statistics to prove that the death rate is highest in those sections of the city where these exist.

**Toronto Hospitals Crowded.**—The Toronto Western Hospital has erected a large tent on its lawns for the accommodation of fifteen tuberculous patients. St. Michael's Hospital is full to overflowing, the corridors having been pressed into service. No patients are being admitted at the present time. Grace Hospital has just completed a new operating theater at a cost of \$10,000, the gift of Lieutenant-Colonel Pellatt. In the Toronto General Hospital there are 325 patients, the largest number in residence at any one time in its history.

**A New Hospital Opened.**—On February 4 there was opened at St. Stephen's, New Brunswick, the Chipman Memorial Hospital by the Hon. L. J. Tweedie, Premier of New Brunswick. This hospital is beautifully situated on the banks of the St. Croix a short distance below the town of St. Stephen's, and was formerly the Chipman homestead. The grounds and buildings, thoroughly equipped with all modern appliances, were presented to the town by Lady Tilley and other heirs of the Chipman estate. It is all ready for immediate use and has accommodation for twenty beds.

**Smallpox in the Province of Quebec.**—The secretary of the Board of Health of the Province of Quebec, Dr. E. Pelletier, has handed out a statement which shows that during the past

year there have been 5069 cases of smallpox in that province. These have been reported from 276 localities in fifty-five out of the seventy-three counties in the province. The percentage of deaths was small, reaching to about one per cent. Three hundred and twenty-four municipalities have notified the Board of Health that they have adopted the compulsory by-laws relating to vaccination promulgated by the provincial health authorities.

#### FOREIGN.

**Escherich Called to Vienna.**—T. Escherich, professor of pediatrics at Graz, has been summoned to the similar chair at Vienna.

**Von Leyden and Kussmaul Enter the Eighties.**—The friends of von Leyden and Kussmaul are preparing to celebrate their eightieth birthdays, the former April 20, and the latter February 22.

**Krafft-Ebing's Successor.**—Professor von Krafft-Ebing retires from the chair of psychiatry at Vienna with the present term. Professor W. von Jauregg has been appointed his successor, and Professor G. Anton takes the place of the latter.

**Jubilee of Professor Tamburini.**—A medal was presented to Augusto-Tamburini, December 15, the occasion being the twenty-fifth anniversary of his professorship. His work at the Reggio-Emilia Asylum for the Insane has made his name prominent among the leading alienists of the world, the founder of a school of psychiatry, which has contributed many important works to science and trained many distinguished alienists.

**Deaths in the Profession Abroad.**—H. Pernice, professor of gynecology at Greifswald.—A. Gougenheim, a prominent laryngologist of Paris, editor of the *Annales des Mal. de l'Oreille*.—Dr. Le Baron, the founder of the Syndicat des Médecins de la Seine.—Dr. Soupart, honorary president of the Federation Med. Belge, died in December at Ghent, in his 92d year. His works on amputations have been numerous and important contributions to science.—Dr. E. Cramer, professor of hygiene at Aachen. Dr. G. Garibaldi, professor of surgery at Genoa.

**The Income of Physicians in France.**—If we are to judge from an item in a recent issue of *The British Medical Journal*, the income of physicians in France is as variable as is the income of medical men in this country. The item referred to is based on a statement recently made by a responsible French writer, M. Chaillisset, from which it appears that there are in Paris 2,600 physicians. Of these, 40 earn from \$40,000 to \$60,000 a year, 50 earn \$20,000 a year, 50 from \$10,000 to \$20,000, 200 from \$6,000 to \$10,000, 200 from \$4,000 to \$6,000, whilst 1700 earn on an average \$620. In the whole of France there are 16,000 practitioners, whose average professional earnings are less than \$600 a year, and this amount does not represent net but gross earnings.

#### LONDON LETTER.

##### The Smallpox Epidemic.

There are now 892 cases in hospital. For the week ending January 18 the number was 877, against 666, 754 and 873 for the 3 preceding weeks; 213 new cases were admitted during the week against 266, 261 and 306 in the 3 preceding weeks. Thus the rate of increase has been checked somewhat. The number of deaths were 55, against 45, 28 and 25 of the preceding weeks. Of 2000 cases which have occurred since August about 200 have occurred in common lodging houses and shelters, and a large number of the remainder among individuals living in tenement houses. The London County Council has taken an active part in the controlling of the epidemic. Their inspectors detected and isolated 44 cases of smallpox in common lodging houses earlier than would otherwise have been possible, and so the spread of the disease was checked. Since the early part of October 41 cases of smallpox have been associated with an antecedent illness said to have been chicken-pox. But this number by no means represents all the cases in which chicken-pox was mistaken for smallpox, as the information was supplied only incidentally. The committee of the London County Council therefore recommend that chicken-pox should be made a notifiable disease in London for 3 months. Probably 500 or 600 cases a week would be notified, which at the rate of 2s 6d a certificate would cost £70 (\$350) weekly. Already 7 of the London boroughs have taken this action.

##### A Scheme for Cancer Research.

Since the King, in his reception of the representatives of foreign countries at the Tuberculosis Congress, referred to the desirability of taking steps to check the ravages of cancer, the

necessity of organization for research has been frequently discussed. At last a project has taken shape and will soon be formally submitted to the College of Physicians and Surgeons for approval. As it has already received the support of eminent men who hold or have held high office in these colleges—the president and censors of the Royal College of Physicians, the president and vice-presidents of the Royal College of Surgeons, Lord Lister, Sir William Broadbent, Sir Richard Douglas Powell, Sir Thomas Smith and Sir John Williams—it will probably be approved of by these bodies. It is proposed to raise a fund to (1) endow laboratories devoted exclusively to cancer research, (2) provide an honorarium for the director of cancer research, (3) provide paid assistants to the director and grants in aid of cancer researches within the United Kingdom or in the British dominions beyond the seas, (4) assist in the development of the cancer research department of the Middlesex Hospital or any other hospital where a cancer research department may be provided, (5) provide for the investigation of any method which may from time to time be brought forward for the prevention, treatment or cure of cancer and arrange for the testing under proper supervision of any so-called remedy for cancer, (6) provide means for systematic investigation of the causes, prevention and treatment of cancer. There will be five trustees, in whose name all moneys will be invested. The income will be administered by a committee consisting of these trustees, the president, and two censors of the Royal College of Physicians, the president and vice-presidents of the Royal College of Surgeons, the laboratory committee of the Royal College of Physicians and Surgeons, and a member of the Local Government Board. It is estimated that \$500,000 will be required. Both the King and Prince of Wales have expressed sympathy with the scheme.

##### Smallpox in Glasgow.

The outbreak of smallpox in Glasgow continues to increase. In hospital are 44 cases and a reception house has been opened in which 35 suspects have been lodged.

##### Sir William MacCormac's Will.

The net personal estate of the late Sir William MacCormac amounts only to \$110,000. His widow is sole executrix and legatee.

##### Plague in India.

The returns for the week ending December 21 show 9198 deaths in all India, against 7795 in the preceding week and 2267 in the corresponding week of last year. One result of the plague is that the city of Bangalore has been largely reconstructed. Of the 10,800 houses, 1922 have been demolished and 5½ miles of new streets have been made. The superintending engineer reports that for symmetry, regularity of frontage, accessibility by the shortest routes, air spaces, public squares, convenience of conservancy and perfect drainage they can be equaled only by some of the most recent cities of America.

#### Married.

J. E. BERRY, M.D., to Miss Anna Taylor, both of Alledonia, Ohio, at Chicago, January 25.

TALBOT C. GERXON, M.D., to Miss Ada A. Kuhns, both of Bloomington, Ill., January 29.

WILLIAM F. GILLAN, M.D., of Pawtucket, R. I., to Miss Josephine Coveney, of Cambridge, Mass., January 29.

WILLIAM B. MURPHY, M.D., of Minneapolis, Minn. to Miss Amelia C. Heiker, a professional nurse, of St. Paul, Minn., at Faribault, Minn., January 29.

HENRY S. WILLARD, M.D., formerly attached to the Topeka Insane Asylum, to Miss Georgia Brooks, both of Manhattan, Kans., at Kansas City, January 29.

#### Deaths and Obituaries.

Paul Fortunatus Munde, M.D., was born September 7, 1846, in Dresden, Saxony. When the boy was 3 years of age his father was exiled from Germany and settled in Florence, Mass. He received his early education in the Latin School of Boston, began his medical studies in the Medical Department of Yale University, but attended his two last courses of lectures at Harvard University Medical School, Boston, and was graduated in 1866. During the Civil war he was acting medical cadet in the army for six months during 1864. After his

graduation he went abroad and served as volunteer assistant-surgeon in the Bavarian service in the war between Prussia and Austria. A year later he became resident physician at the Wuerzburg maternity and was assistant to the German gynecologist, Seanzoni. At the onset of the Franco-German war he offered his services and was made battalion surgeon with the rank of first lieutenant in the German army. After the close of the war he studied in Vienna for nearly two years, and there was given the degree of Master in Obstetrics. After continuing his studies in Heidelberg, Berlin, London, Edinburgh and Paris, he returned to the United States and located in New York City, where he established himself as a specialist in gynecology and obstetrics. In 1874 he became editor of the *American Journal of Obstetrics* and held this position until 1892, when pressure of other duties caused his resignation. He was made professor of gynecology in the New York Polyclinic in 1882, professor of gynecology in Dartmouth Medical College in the summer term of 1880, and was gynecologist to the Mt. Sinai Hospital, St. Elizabeth's Hospital and the Italian Hospital. He was a member of the Medical Society of the County of New York, a fellow of the New York Academy of Medicine, a member and president of the New York Obstetric Society, a member and vice-president of the American Gynecological

PAUL F. MUNDE, M.D.

Society and the British Gynecological Society, a member of the German Gynecological Society, and a corresponding fellow of the Obstetrical Societies of Edinburgh, Leipzig and Philadelphia. He contributed a number of important papers to the literature, and, in addition, was the author of standard works on surgical gynecology and minor surgical gynecology, and, in connection with Dr. Thomas, of a "Practical Treatise on the Diseases of Women." He died at his home in New York City, February 7, after a prolonged illness, from heart disease. He rallied in January and expected to take a trip to the South, but suffered a relapse and steadily declined thereafter.

**John T. Metcalfe, M.D.** University of Pennsylvania, 1843, who died of senility, January 30, at his home in Thomasville, Ga., was for many years in the front rank of his profession in New York City. He was the son of a physician, and was born in Natchez, Miss., in 1818. He graduated from West Point in 1838, and after a short service in the army, resigned to take up the study of medicine, completing his training in Europe. He then came to New York City, where his quickness of perception, readiness in analysis, remarkable memory and keen judgment soon built up a practice. He began in the days before anesthesia and the clinical thermometer, and his calls in those early days were made on horseback. Dr. Metcalfe was a member of the New York Medical and Surgical Society, the County

Medical Society, the New York Society for the Relief of Widows and Orphans, the New York Pathological Society, the New York Academy of Medicine, and the New York Physicians' Mutual Aid Association. He was for many years lecturer at the New York College of Physicians and Surgeons, and at the time of his death he was emeritus professor of clinical medicine. He had retired from practice about fifteen years ago. Dr. Metcalfe had been consulting physician to Bellevue, Roosevelt, St. Luke's and the Woman's Hospitals, to the Hospital of the New York Society for the Relief of the Ruptured and Crippled, and to the New York Orthopedic Dispensary and Hospital.

**Samuel A. Bonesteel, M.D.** University of Michigan, 1867, and McGill University, Montreal, 1870, one of the prominent physicians of Denver, Colo., died at his home in that city, January 29, aged 60, from pneumonia complicating diabetes. Dr. Bonesteel is said to have enjoyed one of the most lucrative practices in Denver for ten years past, and was a member of the Denver and Arapahoe Medical Society and of the Colorado State Society. He was a native of British Columbia, and, before his removal to Denver, practiced in Columbus and Lincoln, Neb. While at Columbus he was one of the chief surgeons of the Burlington and Missouri River railroad, and in Denver was for a time connected with the Denver and Rio Grande road.

**Charles A. Harnish, M.D.** University of Pennsylvania, 1891, died, January 2, at the Presbyterian Hospital, Philadelphia, of laryngeal tuberculosis, aged 35. His death ends a long and successful practice in Alexandria, Pa. He was a member and ex-president of the Huntingdon County (Pa.) Medical Society, a graduate fellow of the William Pepper Medical Society of the University of Pennsylvania, a member of the State Medical Society and of the American Medical Association.

**Henry R. Baldwin, M.D.** College of Physicians and Surgeons, New York, 1853, one of the most prominent physicians of New Brunswick, N. J., where he had practiced for forty years, a trustee of Rutgers College, president of the New Brunswick Board of Health, and a member of the American Medical Association, died at his home in New Brunswick from pneumonia, February 3, aged 73.

**William A. Dudley, M.D.** University of Pennsylvania, 1850, died, February 1, of pneumonia, at his residence in Petersburg, Va., aged 72. He had practiced medicine in that city for nearly half a century, and at one time was a member of the city council. Wealthy, and of one of the first families of Virginia, he had lived alone in most eccentric fashion for many years.

**Edwin Schwartz, M.D.** Rush Medical College, Chicago, 1881, died at his home in Knoxville, Ill., February 4, aged 48, of complications following pneumonia. He was for a long period house physician of the Knox County Almshouse, and was a member of the Military Tract Medical Society and of the American Medical Association.

**Francis M. Black, M.D.** Starling Medical College, Columbus, Ohio, 1852, a prominent physician of Fayette County, Ohio, a veteran of the Civil war, in which he served as captain in the Ninetieth Ohio Volunteers, and president and director of a bank in Washington Court House, died at his home in that place, January 20, aged 74.

**Arthur R. Hagen, M.D.** Tulane University, New Orleans, 1897, of Leger, O. T., died in Dallas, Texas, January 18, from appendicitis, aged 33. Dr. Hagen was a member of the U. S. Marine-Hospital Corps during the yellow fever epidemic at New Orleans, and later went to Cuba as surgeon during the late war.

**Luther W. Allingham, M.D.** Trinity Medical College, Toronto, Ont., 1889, who was obliged to locate in California on account of his health, and practiced at Big Pine and Independence, Inyo County, died at Randsburg, January 29, from consumption, aged 39.

**Joseph Wilkins, M.D.** University of Maryland, 1847, a retired physician, died at Baltimore, February 5, aged 78. After graduation, Dr. Wilkins studied diseases of the eye and ear in Paris, but he practiced only a short time, retiring to devote himself to mining.

**Benson G. Connor, M.D.** Castleton (Vt.) Medical College, 1846, a retired physician, aged 80, of Waxahachie, Texas, died February 1, of injuries received in falling from a window.

**Henry W. Foster, M.D.** Detroit (Mich.) Medical College, 1879, of Bozeman, Mont., died of heart failure at St. Mary's Hospital, Minneapolis, Minn., February 3.

**Zenas T. Garland, M.D.** Medical College of Ohio, Cincinnati,

1871, one of the most prominent physicians in his section of Ohio, died at Clarksville, February 2, aged 60.

**Lock E. Houston, M.D.** Tulane University, New Orleans, 1893, of Aberdeen, Miss., died of heart failure at Memphis, Tenn., January 19, aged 38.

**Alexander L. Williamson, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1883, died at his home in Humboldt, Neb., February 4.

**Walton Saunders, M.D.** University of Maryland, Baltimore, 1856, formerly of Essex County, Va., died in San Francisco, Cal., February 2.

**George W. Hudson, M.D.** Rush Medical College, Chicago, 1870, died at his home in Bethany, Ill., January 21, from pneumonia, aged 59.

**Charles E. Woodward, M.D.** Jefferson Medical College, Philadelphia, 1864, died at New Egypt, New Jersey, January 25, of nephritis.

**Cassius O. Jackson, M.D.** University of Buffalo, 1880, died of pneumonia at the age of 47 at his home in Victor, N. Y., January 26.

**Moses W. Speer, M.D.** Southern Medical College, Atlanta, Ga., 1883, died at his home in Chattanooga, Tenn., aged 46, January 29.

**Irvine W. Gilkeson, M.D.** Jefferson Medical College, Philadelphia, 1868, died in his home at Mint Spring, Va., January 26, aged 58.

**Joseph W. Keene, M.D.** Harvard University, 1878, died at his home in Fallbrook, Cal., January 30, from apoplexy, aged 54 years.

## Correspondence.

### Skilled Anesthetizers.

CHICAGO, ILL., Feb. 5, 1902.

*To the Editor:* In THE JOURNAL of January 25, Dr. Holmes reports a death from chloroform. This report should not be allowed to pass without some comment and perhaps a word of criticism. Scarcely a week passes that does not bring me rumors of deaths or narrow escapes from death from anesthetics, but the reports on such occurrences are altogether too infrequent. We get reports from everything else that happens in surgery, but there seems to be a "conspiracy of silence" which will not allow occurrences in this field to be published. There is no disposition to criticise the person who gave this anesthetic; for all I know he may have been a skilful anesthetizer and every one who administers anesthetics is liable to this experience. Using some of the statements of Dr. Holmes as a text I would like to point out some of the factors which contribute to such deplorable accidents. In the first place, the surgeon and the anesthetizer should be in perfect sympathy and work in harmony. The anesthetizer is naturally anxious to make a good impression on the surgeon the first time they have a case in common and when the patient interferes with the operation by struggling, the anesthetizer feels that he must give more anesthetic in a hurry, and he is likely to carry the anesthesia as far in one other direction. I have many times seen the anesthetized pick up the bottle when the patient began to move and pour on more of the anesthetic than he would dare to use at the beginning of the anesthesia. The patient is already pretty well saturated with the drug and possibly taking deep inspirations from the pain of the operative procedures, and he may get an overwhelming amount of the anesthetic. Concentrated chloroform vapor and deep inspirations form a dangerous combination.

Resuscitation should not be "tardily begun." The anesthetizer must be on the alert every instant, and if he is, trouble can scarcely exist for five seconds without detection. Valuable time should not and must not be lost, whatever is to be done must be done quickly. I hardly see how a patient requiring artificial respiration can safely be taken from one room to another.

The report closes with the remarkable statement that a man who once gives ether is ever after unfitted to give chloroform. I see but one inference to be drawn from this statement, and it is that the anesthetizer thinks the amount of the anesthetic

used is a guide to the patient's condition instead of the patient's condition being a guide to the amount of the anesthetic to be used. I have had too much instruction from Dr. Holmes to believe that he really intended to imply such a thing. If this rule regarding anesthetics is to be observed, then we must insist that a man who has once amputated a leg should never thereafter be permitted to operate upon the neck lest he should carelessly or thoughtlessly amputate the patient's head. Then we will require experts to give gas and experts to give ether, others to give chloroform and still others to give bromid of ethyl and so on to the end of the catalog of anesthetics. Then, as it is sometimes necessary or desirable to use two or three different anesthetics during the course of one operation, we will require at all operations the attendance of as many anesthetizers. There is no doubt that a man may and usually does become more skilful in administering one anesthetic than another, just as an operator becomes more skilful in performing an operation which he does frequently than another which he performs less often; but if a man is expert in the use of one anesthetic he can soon acquire skill in the use of any other. If a man is to be restricted to the administration of but one kind of anesthetic then the anesthetic to be used will depend on who happens to be called in to give it and not on the indications in the case. In other words, the case will be made to suit the anesthetic and not the anesthetic to suit the case. There has been too much of that already in surgery, let us not have it also in anesthetics. I have heard of a doctor who operated on the rectum of every patient who consulted him with little regard to indications in the case, another under the same circumstances would remove the appendix, another the ovaries, another the uterus, the operation being suited to the doctor and not to the case; in other words, the operation or the anesthetic would depend on what doctor a man happened to consult rather than on the disease he happened to be afflicted with. This would be specialism run riot. D. H. GALLOWAY.

## Societies.

**Upper Des Moines (Iowa) Medical Association.**—The fourth semi-annual meeting of this Association will be held at Estherville, February 20.

**Atlantic County (N. J.) Medical Society.**—This Society, at a meeting held February 5, elected Dr. Wm. Edgar Darnall, president; Dr. Theodore Senseman, vice-president; Dr. Edward Guion, secretary and treasurer, and Dr. A. Burton Shimer, reporter.

**Comanche County (Okla.) Medical Society.**—This Society held its annual meeting at Lawton, January 20. Dr. A. X. Campbell was elected president; Dr. F. E. Rosenberger, vice-president; Dr. C. M. Maupin, secretary, and Dr. W. M. Turner, treasurer.

**Morgan County (Ill.) Medical Society.**—The following officers were elected, December 12: President, Dr. P. C. Thompson; vice-president, Dr. David Reid; secretary, Dr. T. A. Wakely; treasurer, Dr. E. F. Baker; and librarian, Dr. T. J. Pitner, all of Jacksonville.

**Cincinnati Obstetrical Society.**—At the last meeting of this Society, Dr. Julia W. Carpenter was elected president; Dr. William Gillespie, vice-president; Dr. Magnus A. Tate, secretary; Dr. Edward S. McKee, corresponding secretary, and Dr. Chauncey D. Palmer, treasurer.

**Harrisburg (Pa.) Academy of Medicine.**—At the annual meeting of the Academy, held January 31, Dr. Hugh Hamilton was elected president; Drs. J. Walter Park, first vice-president; Dr. David S. Funk, second vice-president; Dr. Thomas S. Blair, secretary, and Dr. E. Harold James, treasurer.

**Brashear (Ky.) Medical Society.**—The regular quarterly meeting of this Society was held at Bardstown, Ky., January 21. Dr. W. E. Shepherd, Taylorsville, president; Dr. Joseph L. Pope, Bardstown, vice-president, and Dr. Wiley Rogers, Taylorsville, secretary. The next meeting will be held in Springfield, April 15.

**Alameda County (Cal.) Medical Society.**—At the meeting held in Oakland, January 14, this Society elected the following officers: Dr. Edmund J. Overend, president; Drs. Oliver D. Hamlin, W. Gray Smith and Wilbur J. Wilcox, vice-presi-

dents; Dr. Albert H. Pratt, secretary, and Dr. Charles A. Dukes, treasurer, all of Oakland.

**Steele County (Minn.) Medical Society.**—This Society had its annual meeting and supper at Owatonna, February 4, at which time the following officers were elected: President, Dr. George Schulze, Owatonna; vice-president, Dr. Albert A. Finch, Blooming Prairie; secretary, Dr. Allan B. Stewart, Owatonna, and treasurer, Dr. Warren C. Eustis, Owatonna.

**Aux Plaines Medical Association.**—The association of regular physicians of the western and southwestern suburbs of Chicago which was organized as the Suburban Medical Society, Dec. 27, 1901, has changed its name to the Aux Plaines Medical Association—a name which more clearly expresses its territorial scope. The Association was given a banquet at Maywood, January 24.

**Cripple Creek District (Colo.) Medical Society.**—This Society met in regular monthly session, January 14, in Cripple Creek. The semi-annual election of officers resulted as follows: For president and secretary: Drs. George McKenzie, Victor, and M. D. Gibbs, Cameron, were unanimously re-elected; for vice-presidents: Drs. Wilbur T. Liggett and Magruder, Cripple Creek; and Dr. Haskell M. Cohen, Victor, were elected; for treasurer, Dr. Sipe, Cripple Creek, was elected.

**Chautauqua County (N. Y.) Medical Association.**—At the annual meeting of this branch of the New York State Medical Association, held in Jamestown, January 23, the following officers were elected: Dr. William M. Bernus, Jamestown, president; Drs. Orrin C. Shaw, Cassadaga, and Era M. Scofield, Jamestown, vice-president; Dr. Henry A. Eastman, Jamestown, secretary and treasurer; Dr. H. Francis Hunt, Dewittville, chairman of the executive committee, and Drs. Walter Stuart, Westfield, Thomas D. Strong, Westfield, and Henry A. Eastman, Jamestown, fellows of the State Medical Association.

**Medical Society of the District of Columbia.**—At the meeting of the Society, held on the 29th inst., Dr. W. W. Johnson read a paper on "The Diagnosis and Treatment of Influenza and Pneumonia." Dr. Acker presented an interesting case and specimen of tuberculosis. Dr. Franzoni presented a case and specimen of malignant disease of the lungs and rib. Dr. Bowen reported a case and specimen in the interest of conservative gynecology in a young girl 17 years of age. He removed an ovarian cystic tumor from one side and a cyst of the tumor on the opposite side, leaving a portion of the healthy ovary and the tubes. The president, Dr. S. S. Adams, announced the following standing committees for the year: Public health, J. W. Chappel, chairman; essays, T. C. Smith, chairman; editing transactions, D. S. Lamb, chairman; executive, W. W. Johnson, chairman. The president has organized a committee on prize essay, and secured the necessary funds by subscription. The competition will be open only to the younger men of the society, those graduating since 1890. It is proposed to give an annual prize of \$100 for the best essay written in competition during the year. Especial arrangements for awarding the prize and passing upon the merits of the essay will be decided by a sub-committee of the executive committee.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*Ninety-sixth Annual Meeting, held in Albany,  
Jan. 28-30, 1902.*

*(Concluded from page 413.)*

The President, Dr. Henry L. Elsner, of Syracuse, in the Chair.

### The Constitutional State versus Catarrhal Deafness.

DR. SARGENT F. SNOW, Syracuse, presented a very important and practical aspect of the treatment of these cases, but one that was too often overlooked or its importance underestimated. Personal hygiene was considered by him as of the very first importance, for an inactive skin or a torpid liver would often effectually thwart the best efforts at local treatment.

DR. J. O. ROE thought that nine-tenths of the cases of "colds" were caused by functional derangements of the internal organs rather than by exposure to cold.

DR. EDWARD B. ANGELL, Rochester, in a paper on "Educational Management of the Neurasthenic," spoke of the value of suggestion, and of the necessity for a carefully graded system of education for this class of invalids.

DR. E. F. BRUSH, Mount Vernon, reported "An Epidemic of Typhoid Fever in the Backwoods of Maine," which was of inter-

est because of its isolation, and also because the boy first taken sick infected others in the family by drinking from a barrel of water and throwing some of the water back.

DR. A. T. BRISTOW, Brooklyn, in connection with the report of a "Case of Strangulated Hernia of the Left Ovary and Tube," said that in many of these cases there were other congenital defects, especially of the genital tract. The inguinal variety was most common, but all cases of hernia of the ovary require operation.

### Toxic Dosage in the Treatment of Some Nervous Diseases.

DR. WILLIAM C. KRAUSS, Buffalo, read a paper with this title. He asserted that the usual dosage given for highlorid of mercury, for example, i. e., 1/20 to 1/10 of a grain, was of no avail in cases of brain syphilis. Here the drug should be given hypodermically in doses of one or two grains daily, and if so given the gummata would quickly melt away. Although the ordinary dosage of Fowler's solution of arsenic was from one to ten minims, he had obtained good results in some cases of chorea from giving 30 to 60 minims, three times a day. In certain neuralgic and neuritic disorders marked benefit would result from giving large doses of nitroglycerin.

DR. HENRY R. HOPKINS, Buffalo, said that during the past year he had obtained exceptionally good results in the treatment of severe cases of delirium tremens by a venesection of one or two pints, followed immediately by infusing double the quantity of normal salt solution.

DR. CARL BECK, New York City, said that in the "Pathology of the Tissue Changes Caused by the Roentgen Rays," after prolonged exposure the hair would be found altered in structure, and the blood vessels of the integument narrowed in caliber.

DR. LUCIEN HOWE, Buffalo, exhibited a head-rest useful in connection with "The Position of the Eye at Rest," and said that, in order to find the position of the eye the light should be allowed to fall on the macula of one eye, and then by interposing a prism, the image of the other eye would be thrown off the macula. As there was no tendency to fusion, under such conditions, the eye would assume the position of greatest ease.

DR. A. D. LAKE, Gowanda, read a paper on the "Civilized Indian; His Physical Characteristics and Some of His Diseases." He showed how the Iroquois Indians had degenerated physically since they had adopted the manners and customs of their civilized neighbors, and said that many of them die young, and that they show a special susceptibility to tuberculosis. On the other hand, they had become practically immune to syphilis, though there was evidence that it had raged among them years ago. Another effect of civilization had been to largely increase the diseases peculiar to women.

### Symposium on Paresis.

DR. ARTHUR W. HURD, Buffalo, opened the symposium by a consideration of the etiology. He quoted statistics from many sources to prove the important part played by syphilis, as well as to show that in places where syphilis was rare paresis was correspondingly infrequent. It was probable that the great mental strain of the present age was also an important factor.

DR. FRANCIS X. DERCUM, Philadelphia, contrasted the symptoms of the neurasthenic with those observed in the early stage of general paresis. The symptoms of the neurasthenic were almost wholly subjective; the patient was anxious to describe them. He was usually worst in the morning and best late in the day; on the other hand, the paretic rarely sought medical advice of his own volition; he left it to others to describe and point out his deviations from the normal. He was at his best early in the day, while in the evening defects of speech and mentality might be present that were not discoverable in the morning. He early exhibited fatigue, impairment of memory, and an indifference to the details of everyday life, and was occasionally guilty of breaches of etiquette. Perhaps the most characteristic sign was the peculiar manner of the paretic: the slight changes in the expression of the face, and the gestures which indicated that he was not in close touch with his surroundings.

DR. CHARLES G. WAGNER, Binghamton, took up the "Comparative Frequency" of the subject. He said that, according to Dr. Bell, of the McLean Asylum, paresis had not come under his observation in this country until after 1840, though he had seen many cases abroad. According to the reports of the Lunacy Commission, 49,787 persons had been admitted to the hospitals of the state, and of this number, 3307, or 6.6 per cent., were cases of paresis. In the Manhattan State Hospital, where more than two-thirds of the inmates are of foreign birth, the records show a remarkable preponderance of the disease among native Americans. The disease was gradually increasing in frequency.

DR. EDWARD COWLES, of Boston, Mass., considered the "Treatment of Paresis; Its Limitations and Expectations," and stated that the limitations of treatment were evident from a lack of a rational basis for our therapeutics. Hospital experience was opposed to the use of antisyphilitic medication except in cases in which syphilis was actively present. Tonics, and hydrotherapy were useful.

DR. GEORGE THOMAS JACKSON, New York City, read a brief paper on "Ringworm; A Note on Its Treatment." The most effective remedy for ringworm of the hairy parts that he had ever used was an ointment composed of one dram of crystalline iodine to one ounce of genuine goose-grease. It should be applied twice a day until there is a little swelling of the patches, and then once daily until cured. No epilation is necessary.

#### Case of Epilepsy with Possible Medicolegal Complications.

DR. FREDERICK SEFTON, Auburn, reported this case. The patient had developed epilepsy after having been very roughly handled by some college mates who were initiating him into a secret society. He apparently recovered quickly, but some months later became moody and irritable, and then suddenly one evening shot at his sister. The next day he was again almost himself, but he never was able to recall any of the happenings of that eventful night. He was finally given the position of purser on a ship, still occupied that position, and had apparently recovered. The case was interesting because it was evident that, under the present mode of procedure in court, it would have been easy to secure testimony as to this man's responsibility for his acts.

DR. WILLIAM BROWNING, of Brooklyn, said that where fright was the cause of epilepsy the latter usually developed within a few hours or days. These patients with psychic epilepsy rarely do violence to others unless interfered with.

#### Leucocytes as an Aid to Diagnosis and Prognosis.

DR. THOMAS R. BROWN, Baltimore, placed the normal number of leucocytes at 6500 to the cubic millimeter. He said that the leucocyte count had proved very useful in connection with typhoid, malaria, tuberculosis, influenza, scarlet fever, diphtheria and pneumonia. The absence of leucocytosis in an uncomplicated tuberculosis served to differentiate it from other diseases, while its presence pointed to secondary infection. There was reason for believing that the leucocyte count may, in the future, aid in detecting secret drug habits. In cases of appendicitis it was of great value to the surgeon.

#### The Value to the Physician of Modern Methods of Diagnosis.

DR. HENRY L. ELSNER, of Syracuse, delivered the Presidential Address. He spoke of the advances made in the diagnosis of diseases of the stomach by chemical analysis of the stomach contents, the determination of the size and contractility of the organ, and its location in the body. The benefit derived from the use of the iodids in syphilitic disease of this organ and the intolerance under other conditions was mentioned as a useful point in differential diagnosis. The speaker then considered the aid that had been derived from the use of the centrifuge, the value to the surgeon of the x-rays, and their possible help to the physician. After speaking at length upon the new science of hematology, he closed by urging general practitioners to take advantage of these new methods of precision.

DR. SAMUEL M. BRICKNER, New York City, in a paper on a "New Symptom in the Diagnosis of Dystocia Due to a Short Cord," said that the occurrence of urination with the cessation of each pain during the second stage he had come to look upon

as a pathognomonic sign of a short funis. If to this were added a marked and jerky recession of the head of the fetus with the ending of each uterine contraction, one might feel quite sure that the cord was unduly short.

#### Symposium on Diseases of the Pancreas.

PROF. R. H. CHITTENDEN, New Haven, Conn., opened this symposium by a consideration of the physiology. He described the production of experimental pancreatic diabetes, and the deductions therefrom, and added that to the physiologic chemist the auto-intoxication theory of diabetes seemed plausible.

DR. W. S. THAYER, Baltimore, said that interference with the digestion of albuminoids was suggestive of pancreatic disease. Acute pancreatitis was associated with agonizing epigastric pain, tenderness and rigidity of this region, an acceleration of the pus and sometimes with cyanosis. Collapse and death often occurred in four or five days. Some had claimed that it was possible to find a fat-splitting ferment in the urine; if so, we would have the first definite sign of pancreatitis. The diagnosis of chronic interstitial pancreatitis was rarely possible.

DR. ROSWELL PARK, Buffalo, described the various routes by which the pancreas might be reached, and pointed out the danger of wounding important vessels and nerves. The route usually selected was in front through the gastrocolic omentum. Posterior drainage would usually be required. The treatment of acute pancreatitis was virtually that of peritonitis of the upper abdominal cavity, and consisted in prompt drainage.

DR. GEORGE BLUMER, Albany, said that in many cases of diabetes the pancreas appeared normal, except for a hyaline degeneration of the islands of Langerhans. It was now believed that the true cause of fat necrosis was the presence of the fat-splitting ferment, and any pancreatic lesions allowing of the escape of this ferment might cause fat necrosis.

DR. JOSEPH C. BLOODGOOD, Baltimore, in a paper on "Clinical Indications for Surgical Interference in Acute Pancreatitis," said that before abscess formation operation was contraindicated, but after its occurrence no time should be lost in establishing drainage. Out of 39 cases of pancreatic abscess the onset in 23 had been very acute, the symptoms being those of acute pancreatitis. Six out of 24 cases operated upon recovered.

DR. DENSLOW LEWIS, Chicago, presented in this paper an account of a large number of curious "Traumatism of Pregnancy," and of remarkable recoveries from the same.

DR. ARTHUR W. ELTING, Albany, in a paper on "Tendon Transplantation in the Treatment of Paralytic Deformities," said that tendon transplantation should not be done so long as there was evidence of spontaneous improvement. It was especially useful in loss of muscles and tendons from injury, in spinal infantile paralysis, in spastic paralysis, and certain congenital deformities, such as club-foot.

DR. J. MILTON MABBOTT, New York City, reported a case of "Pneumogalactoele, with an Unidentified Organism," in which the breast of a primiparous woman became the seat of a tumor containing milk and gas. It developed at the end of the third week. Bacteriologic examination showed the presence of a micro-organism, which was apparently non-pathogenic, but it could not be identified.

DR. ROWLAND G. FREEMAN, New York City, in an essay on a "Simple Method for Determining Percentage of Milk in Home Modifications," endeavored to simplify the calculations by eliminating algebraic formulae, noting the proportion between the fats and proteids, and then selecting a cream containing the same proportion. Thus, with the formula, fat 3, sugar 6, proteids 1, the proportion is 1 to 3; therefore 12 per cent. cream should be used as the basis, diluting it with water. The sugar is added separately.

#### Banquet.

The evening was the occasion of an unusually enjoyable banquet. No less than 319 took part, and made merry to a late hour. Governor Odell made an address, in which he begged them not to be unduly anxious about the osteopathy bill, for, if it should happen to slip through the legislature, he would take care of it. He would hardly have taken them so much into his confidence if it had not been that that very afternoon

the public hearing on this bill had been given, and the osteopaths had made a very feeble showing.

DR. HEINRICH STERN, New York City, read a paper on "Obesity of Adolescence." He divided these cases of obesity into those disappearing at the approach of maturity and those continuing after full development had been reached. The latter class he designated as "metabolic," and asserted that they were dependent upon faulty thyroid or parathyroid activity. Neither variety of obesity demanded treatment unless the weight was excessive. In the advanced metabolic cases the treatment was mainly dietetic.

DR. REGINALD H. SAYRE, New York City, read some "Observations on Broken Necks," and exhibited a series of plates illustrative of this class of cases. If the upper three vertebrae were involved, the head would usually assume the position of a torticollis, but in some instances there was an obliteration of the normal curve of the back of the neck. The vertebrae required support for a much longer time than was generally believed. A good plan was to envelop both head and chest in plaster of paris.

#### Election.

To State Board of Examiners: Dr. A. Walter Suiter, of Herkimer, and Dr. George R. Fowler, of Brooklyn.

Officers of Society: President, Dr. Henry R. Hopkins, Buffalo; vice-president, Dr. William A. Moore, Binghamton; secretary, Dr. Frederic C. Curtis, Albany; treasurer, Dr. O. D. Ball, Albany.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, XIII.

(Continued from page 419.)

#### Inhalations and Atomization.

It is yet a question as to just how much of the respiratory tract is reached by these two methods. That good results can be obtained by this form of treatment in dealing with diseased conditions of the nasal mucous membrane of the pharynx, larynx, trachea and upper bronchi, there can be no doubt. Volatile preparations may be vaporized and the vapor inhaled; non-volatile substances may be dissolved in any good menstruum and, when placed in an atomizer, made to form a very fine spray. The vehicle or menstruum may be liquid petrolatum, glycerin or water. Powders may be employed by means of insufflation.

The following combinations are recommended by E. Fletcher Ingals as local treatment in the different diseases of the respiratory tract:

#### AS AN INHALATION.

|                   |       |      |
|-------------------|-------|------|
| R. Formalin ..... | m. xv | 1    |
| Menthol .....     | 3ss   | 2    |
| Tinct. iodi ..... | 3ii   | 7 50 |
| Alcoholis .....   | 3i    | 30   |

M. Sig.: Use in a small inhaler four or five times a day, continuing five minutes each time. This is used in cases of chronic laryngitis and laryngo-trachitis and for five minutes at each inhalation or until the patient can feel its effects in the trachea for several minutes after stopping the inhalation. If this does not seem strong enough the following may be used:

|                   |       |       |
|-------------------|-------|-------|
| R. Menthol .....  | 3i    | 3 75  |
| Formalin .....    | m. xx | 1 33  |
| Tinct. iodi ..... | 3iii  | 11 25 |
| Alcoholis .....   | 3i    | 30    |

M. Sig.: Use as an inhalation four or five times daily.

In cases of subacute laryngo-trachitis the following is sometimes employed:

|                               |    |    |
|-------------------------------|----|----|
| R. Tinct. benzoini comp. .... | 3i | 30 |
|-------------------------------|----|----|

Sig.: Pour a teaspoonful in a small vessel of hot water and allow the patient to inhale the vapors by placing the mouth

over the vessel and covering the head with a cloth in order to retain the vapors. This may be repeated every two or three hours if necessary.

The following is used as an inhalation in cases of acute and subacute trachitis and bronchitis:

|                      |        |    |
|----------------------|--------|----|
| R. Thymol .....      | gr. ss | 03 |
| Menthol .....        | gr. x  | 66 |
| Liq. petrolati ..... | 3i     | 30 |

M. Sig.: Place in an inhaler and use two or three times daily.

As a spray to be used in an atomizer:

|                             |       |    |
|-----------------------------|-------|----|
| R. Iodi (5 per cent.) ..... | m. xv | 1  |
| Menthol .....               | gr. x | 66 |
| Liq. petrolati .....        | 3i    | 30 |

M. Sig.: Use as a spray once or twice daily.

The foregoing is used in cases of chronic laryngitis, pharyngitis and in rhinitis accompanied by dryness of the membranes. It may also be employed when chronic inflammation of the Eustachian tube is present by directing the spray into the posterior pharynx.

In order to check the secretions in cases of chronic rhinitis with excessive watery discharge the following spray may be used:

|                           |         |      |
|---------------------------|---------|------|
| R. Olei caryophylli ..... | m. viii | 50   |
| Terebeni .....            | m. xx   | 1 33 |
| Liq. petrolati .....      | 3i      | 30   |

M. Sig.: Use as a spray three or four times a day.

In the more acute forms of rhinitis the following:

|                          |       |    |
|--------------------------|-------|----|
| R. Acidi carbolici ..... | gr. i | 06 |
| Menthol .....            | gr. i | 06 |
| Olei gaultheriae .....   | m. i  | 06 |
| Liq. petrolati .....     | 3i    | 30 |

M. Sig.: As a spray four or five times a day.

Yeo, in his *Clin. Ther.*, recommends the following combinations in the treatment of the different forms of bronchitis:

#### BRONCHORRHEA AND FETID BRONCHITIS.

|                         |      |      |
|-------------------------|------|------|
| R. Acidi carbol. ....   | 3ss  | 7 50 |
| Tinct. opii camph. .... | 3iii | 90   |

M. Sig.: A teaspoonful to be inhaled freely from half a pint of hot water; or:

|                             |         |      |
|-----------------------------|---------|------|
| R. Acidi carbol. ....       | m. viii | 50   |
| Olei pini prunilionis ..... | m. xx   | 1 33 |
| Aque. q. s. ad. ....        | 3i      | 30   |

M. Sig.: To be diffused from the surface of water kept boiling.

The following is recommended by him as an antiseptic in fetid bronchitis:

|                         |     |      |
|-------------------------|-----|------|
| R. Thymol .....         | 3i  | 3 75 |
| Acidi carbol. ....      | 3ii | 7 50 |
| Creosoti .....          | 3ii | 7 50 |
| Spts. chloroformi ..... | 3i  | 30   |

M. Sig.: As an inhalation.

(To be continued.)

#### Nasal Ointment.

In crust formations upon the septum, and upon eroded surfaces which may have even gone so far as to produce perforation of the septum, the following ointment is of service:

|                      |         |      |
|----------------------|---------|------|
| R. Zinci oxidi ..... | gr. xl  | 2 66 |
| Acidi carbol. ....   | gr. vi  | 40   |
| Olei rosae .....     | m. v    | 32   |
| Iodol .....          | gr. xxv | 1 66 |
| Lanolini .....       | 3iv     | 15   |

M. Sig.: Apply locally to the affected parts.

#### Terpin Hydrate in Bronchitis.

The following combination containing terpin hydrate is recommended in troublesome coughs:

|                                |        |        |
|--------------------------------|--------|--------|
| R. Terpin hydratis .....       | 3ss-3i | 2-3 75 |
| Glycerini .....                | 3ii    | 7 50   |
| Alcoholis .....                | 3v     | 18 75  |
| Elix. simplicis q. s. ad. .... | 3iv    | 120    |

M. Sig.: One teaspoonful every three or four hours in water.

### Antipyretics in Children.

McGee, in *Cleveland Med. Gaz.*, states that there is frequently no need of reducing fevers in children, but when he does use an antipyretic of this group his preference is for phenacetin. He gives one to three grains to a child two to five years of age. According to Hare antipyrin is safest, especially in treatment of the paroxysms of pertussis. It may be given in doses of two or three grains daily for each year of the child's age. Phenacetin, however, is more useful as a sedative in the treatment of influenza in children.

### Treatment of Warts.

Dr. Courbin, as noted in *Pract. Druggist*, states that he has successfully used the following method in removing warts: The skin of the part is carefully disinfected; the base of the wart is transfixed by two needles (rendered aseptic) at right angles to each other. A piece of aseptic silk is then tied tightly around the base of the wart below the needles; the tightening of the ligature constricts the warts, forming a pedicle, and an antiseptic powder is dusted on. At the end of eight days the dressing is removed, when the warts, needles, and silk come away, leaving a small wound, which soon heals.

### Treatment of Contagious Diseases of the Eye.

Ziegler, as stated in *Amer. Med.*, discusses the treatment of contagious diseases of the eye by the general practitioner. He states that the local treatment of acute catarrhal conjunctivitis consists of a single application of silver nitrate, grains 5 to the ounce, on the first day, followed by milder applications of glycerol of tannin or a 10 per cent. solution of protargol on each successive day. The following wash is of value:

|                          |       |    |
|--------------------------|-------|----|
| R. Sodii biboratis ..... | gr. v | 30 |
| Acidi borici .....       | gr. x | 66 |
| Aquæ rosæ .....          |       |    |
| Aquæ destil. āā .....    | ℥i    | 30 |

M. Sig.: Drop in each eye freely every two or three hours.

Granular conjunctivitis should be treated daily by an application of silver nitrate, from 5 to 10 grains to the ounce. When the disease begins to yield, milder applications, such as glycerol of tannin or boroglycerid (50 per cent. solution) should be substituted. Purulent ophthalmia should be treated by the daily application to the everted eyelids, of a 10-grain solution of silver nitrate, neutralized by a saturated solution of salt followed by an after irrigation of bichlorid wash. Ice compresses should be applied to the lids, and changed every minute until the swelling and discharge are markedly diminished. A 1 to 4000 bichlorid solution should be used as a wash every fifteen minutes for the first three or four days and then at longer intervals a 1 to 8000 solution may be used. Twice daily a solution of protargol (10 to 25 per cent.) should be instilled. As a prophylactic measure in ophthalmia neonatorum a single drop of a 10-grain solution of silver nitrate may be instilled, or the eyes may be irrigated with a 1 to 4000 bichlorid solution, or a solution of protargol 10 to 25 per cent. may be used.

### As an Antiseptic Mouth Wash.

The following is recommended by *Merck's Report* as a mouth wash:

|                       |        |    |    |
|-----------------------|--------|----|----|
| R. Formalin .....     | m. v   | 3  | 75 |
| Tinct. benzoini ..... | ℥iii   | 11 | 25 |
| Tinct. myrrhæ .....   | ℥i     | 3  | 75 |
| Olei menthæ pip. .... | m. iii |    | 20 |
| Olei anisi .....      | m. ii  |    | 13 |
| Olei cassiæ .....     | m. i   |    | 06 |
| Olei cinnamomi .....  | xv     | 1  | 00 |
| Alcoholis .....       | ℥ii    | 60 |    |

M. Sig.: Use as mouth wash once or twice daily.

## Medicolegal.

**Fracture of Ankle Bone and Septic Pneumonia.**—The Court of Appeals of New York says that the only serious question presented in the case of *Seifert vs. the Brooklyn Heights Railroad Company* was whether the guessing of medical experts, based upon inaccurate hypothetical questions, to

the effect that a broken bone in the ankle, which did not perforate the skin, caused septic pneumonia four and one-half months afterwards, furnished sufficient support for a verdict of a jury awarding damages against the negligent party for the resulting death. Death from pneumonia, it says, is not ordinarily the necessary and natural result of an injury to the fibula bone, and when, as it was in this case, it is sought to establish, almost entirely by expert evidence, that such result actually followed, the connection between cause and effect should be made so clear that the conclusion can be said to be the reasonable result of the proof. In this case the proof fell far below that standard, and the verdict of the jury was left, the court declares, too largely upon conjecture and speculation, and so, it thinks, was not supported by evidence, wherefore the verdict should not be allowed to stand.

**Sale of Drugs by Physician.**—Section 2620 of the Kentucky statutes makes it a misdemeanor to sell or compound drugs, except for a registered pharmacist, or under his immediate supervision. Section 2632 provides, "Nothing in this act shall apply to, or in any manner interfere with the business of any licensed practicing physician, or prevent him from supplying to his patients such articles as may seem to him proper, or with his compounding his own prescriptions." It will be seen, the Court of Appeals of Kentucky says, in the case of *Commonwealth vs. Hovious*, that this section does not, simply in general terms, exempt physicians from the provisions of section 2620. The true meaning and intent of section 2632, in the court's opinion, is to allow a physician to compound or sell any kind of drugs to his own patients, but not to fill prescriptions sent to him by others. In other words, if a party applies to a physician for examination and treatment, the physician, the court holds, may furnish him any kind of drugs that in his judgment is proper, or compound for him any kind of drugs or medicine; but he can not sell drugs indiscriminately to persons calling for the same, nor compound drugs and sell them indiscriminately to all who may call for them. It results, it holds, that it was error to adjudge not guilty of violating section 2620 a regular licensed physician who carried on the business of a retail druggist in person and by an agent, without obtaining the certificate required by law of pharmacists.

**Liability for Failure to Furnish Medical Assistance.**—The Court of Civil Appeals of Texas says that, according to testimony in *Galveston, Harrisburg & San Antonio Railway Company vs. Rubio*, the company violated its contract in regard to furnishing the latter party, who had been in its employ, with necessary medical and hospital assistance. For such breach of contract the man, the court holds, would be entitled to recover to the extent of the damages he may have sustained, which might be expected as naturally resulting from such breach. In other words, the company would be responsible if it violated said provision of its contract to compensate him in reference to his immediate sickness, and the consequences thereof attributable to its failure to give him the necessary attention; and loss of time, and decreased capacity to earn a living, the court says, could not be regarded as too remote. But, as a matter of damages, his act in making his way back to his home, some 700 miles, on foot, was too remote to be considered, though occasioned by his having no money to pay his fare. It says that this act had no connection with the company's refusal to comply with its contract, as a natural result thereof, nor was it an act to be reasonably expected therefrom. The rule that, where there is serious physical injury occasioned by the act of another, mental suffering, if any, may also be considered as an element of damages, the court holds, had application in this case. It says that although the damages sought were for breach of contract, it will be observed that the very subject-matter of the contract was the health or physical condition of the employee. From a breach of it physical suffering and injuries would naturally follow. Hence, the applicability of the rule.

**Louisiana Medical Practice Act Not Unconstitutional.**—The title of Louisiana Act No. 49 of 1894 reads: "An act to regulate the practice of medicine, surgery and midwifery; to create state boards of medical examiners, and to regulate

the fees and emoluments thereof; to prevent the practice of medicine, surgery and midwifery by unauthorized persons; and to provide for the trial and punishment of violators of the provisions of this act by fine or imprisonment, or both; and to repeal all laws or parts of laws in conflict or inconsistent with this act." Section 12 provides "that any itinerant vender of any drug, nostrum, ointment or application of any kind, intended for the treatment of disease, or injury, or who may by writing, print, or other method, profess to cure or treat disease, or deformity, by any drug, nostrum, manipulation, or other expedient, in this state, shall, if found guilty, be fined in any sum, not less than \$25, and not exceeding \$100, for each offense, to be recovered in an action of debt before any court of competent jurisdiction, or shall be imprisoned for a term of not less than ten days or more than thirty days, or both fined and imprisoned." The Supreme Court of Louisiana holds, *State vs. Lee*, that the title expresses but one object, and that section 12 does not go beyond the title, by denouncing the mere selling of drugs and nostrums, etc., as an offense; the offense there denounced consisting of the itinerant vender professing to treat and cure disease and deformity by the use of drugs, nostrums, etc., sold by him, and by the other means mentioned. It says that it can hardly be denied that, if the general purpose of the act is to protect the public from unskilled and incompetent practitioners, provisions relating to vendors who undertake to prescribe and effect cures with the nostrums which they sell are quite as germane to the purpose as the provisions which relate to persons who, without having had their qualifications tested, undertake to treat disease by the use of compounds sold by others. It does not think that the section was intended to apply to the itinerant vender, merely in his capacity of vender, but that, as above suggested, the lawmaker was undertaking to deal with him, for the purposes of the act, as a person professing to treat or cure disease or deformity by the use of drugs and nostrums which he sells, or by manipulation or other expedients. Nor, although the section is inartificially drawn, does the court consider that it can be interpreted as defining and denouncing two offenses: the one, of selling, and the other, of professing to cure with, drugs and nostrums. It ignores the disjunctive "or" after the word "injury."

1. **Modern Methods of Diagnosis.**—Elsner's address covers the subject of the modern improvements in diagnosis which are becoming so numerous and important in medical practice. Of course, not all the newer methods are referred to. He says the individual has the right to demand of his physician, after recording all facts relating to the disease, the investigation of every detail of his case by every method needed for accurate observation and ultimate diagnosis.

2. **Erysipelas in the Negro.**—The rarity of erysipelas in the negro in the literature of the disease suggested to Stoops the report of a case of spontaneous erysipelas in a coal-black

negro woman with typical symptoms and course, with streptococci in the blebs. He briefly reviews cases reported in the literature and offers as his conclusions the following: 1. The negro possesses no special immunity against erysipelas. The impression that he is immune is due to the following causes: *a.* The average physician does not have an extensive practice among the negroes. *b.* In the North, negroes frequently have a superstitious dread of a hospital, and hence do not always apply for treatment. *c.* The physicians who have had such cases have not, as a rule, reported them. *d.* The disease is sometimes unrecognized when it does occur. 2. As interpreted by the course the disease took in my case, the picture of facial erysipelas in a negro is the following: *a.* The onset is attended with enlargement of the cervical glands, sore throat and high fever. The swelling generally begins around the nose or mouth. *b.* No cutaneous flush is visible in a very dark negro. *c.* Hardened projections can be felt at the periphery of the inflamed area. *d.* The blebs, which occurred early in my case, are very distinct, showing as whitish patches in sharp contrast with the dark skin. *e.* Desquamation begins in a part as soon as the inflammation has subsided, and may be complete in one place while the erysipelatous process is active in another. *f.* The general symptoms are those that accompany most of the acute fevers.

4. **The Stationary Ophthalmoscope.**—Hansell illustrates the Thorner stationary ophthalmoscope and shows its use for fundus examination. It can not, of course, replace the hand ophthalmoscope for various reasons, viz.: its size, non-portability, inferiority in the study of lens and vitreous opacity and its indifferent measurement of the state of refraction of the eye, but it is specially valuable in the examination of the fundus and in the teaching and sketching or painting diseased or healthy eye grounds and in diagnosis.

5. **Vaccination.**—Runyon gives a very unfavorable opinion of the use of the glycerinated vaccine, maintaining that there are several possible reasons why it should be more likely to be followed by tetanic infection. He enumerates these as follows: 1. In making the glycerinated virus, parts of the vesicle are used, which were formerly considered unsafe. 2. The germs of tetanus being anaërobic and very resistant to ordinary germicides, possibly find suitable media in the liquid virus (for, so far as I have been able to learn, tetanus when it occurred has almost invariably followed the use of this virus). The incubation period seems to exclude this. 3. Glycerinated lymph is slow in drying, and may thus become contaminated by germs floating in the air, from clothing, etc. 4. This is a point to which I call special attention. The germs of tetanus almost invariably require the assistance of other germs to prepare the soil, else they will not develop (Dereum-Keating's *Cyclopaedia-Supplement*). May not the slough (superficial gangrene, for such it is) not infrequently following the use of certain types of the glycerinated lymph, supply the ideal soil? Then the tetanus germs develop, if present in the vaccine, or otherwise reaching the wound. He reiterates his view that he thinks it is a dangerous virus for general use and one calculated to bring discredit upon vaccination generally, a statement which he made in August and claims that it was a prophecy that has been fulfilled.

7. **Digital Examination in Labor.**—Briggs recommends the use of rectal instead of vaginal examination in labor and claims that equally satisfactory results have been obtained as to presentation, etc., as by the other method, without the risk of introducing germs or interfering with the natural secretions.

8. —See ¶1 above.

9. **Adrenalin.**—Herter and Richards have found that adrenalin solution injected into the peritoneal cavity of a normal dog causes a rapid and usually considerable excretion of dextrose in the urine, an observation not heretofore made. The details of the experiments are reported and attention called to special points. In one case an effort was made to greatly reduce the carbohydrate material by means of injections of phloridzin, together with deprivation of food. It is noticeable that urine collected four hours after the injection did not contain any sugar, though later glucose appeared in small amounts.

Another feature of interest is that abundant excretion of glucose followed the injection of adrenalin solution when it had been boiled for five minutes, which process must have destroyed any diastatic ferment contained in the extract. In fact Takamine's method of preparing adrenalin makes unlikely the leaving of any diastatic ferment in the product. It also can be added to the solution of glycogen and kept in an incubator for twenty-four hours without conversion of glycogen into sugar. From these facts they hold that there is no reason for attributing the glycosuria from adrenalin to the presence of a diastatic ferment. There is also no satisfactory reason for referring to the diastatic ferment in the suprarenal body the glycosuria caused by an extract of this gland. The dogs which received the adrenalin subcutaneously showed only slight increase in the reducing substance of the urine, which contrasted sharply with doses of equal size given intraperitoneally. The alterations in the intestines and pancreas in one experiment are remarkable and indicate that the agent is capable of producing highly destructive changes of the parts. After a fatal dose of adrenalin the cells composing the islands of Langerhans were found to be the seat of granular degeneration, very pronounced in some places. The nuclei of many of these cells showed extensive loss of chromatin substance. In some parts of the pancreas the cells of the islands of Langerhans were much more injured than the surrounding cells of the secreting acini. The authors promise to investigate these results more fully. They suggest, however, that this glycosuria is in reality of pancreatic origin, though such advanced pancreatic lesions are not essential to its production.

10. **Isthmus Canals.**—Stubbert reviews and criticises the paper of Soper published in the *Medical News* of January 4, calling attention to the different sanitary conditions along the Panama and Nicaragua routes. While the Panama route is undoubtedly deadly he gives numerous facts to show that the Nicaragua route is comparatively a healthy one.

12.—See ¶1 above.

13. **Suggestion in Medicine.**—The importance of suggestion is illustrated by numerous instances by Smith, who calls attention to the danger of evil results from careless remarks of physicians or from the lack of sufficient instruction. He thinks that the fact of human suggestibility necessitates in the physician more thorough study of human nature and psychology. We should make our examination more exhaustive and sharpen our observation with the result of producing better diagnosis, prognosis and treatment. The two points which he specially wishes to emphasize are the need of thorough psychologic preparation for the medical school and the dangers of bad suggestive therapeutics.

15. **Vaccination.**—The importance of vaccination and revaccination is insisted upon by Durgin, who makes, however, an interesting statement in regard to the Mexican practice of using only humanized lymph and never revaccinating with excellent results as regards prophylaxis from smallpox. He thinks only slight abrasions, perhaps not over  $\frac{1}{8}$  to  $\frac{1}{4}$  of an inch in diameter, are required and the skin should be only reddened; drawing blood is useless.

16. **X-Ray Diagnosis of Foreign Bodies in the Eye.**—Sweet discusses the value of x-ray diagnosis, its accuracy, etc., from a study of some 65 cases in which the foreign body was shown on examination out of a total of 102 cases examined and offers the following conclusions: "1. The Röntgen rays offer the most certain method of detecting and locating foreign bodies in the eye. 2. The position of the foreign body should be determined in all cases before magnet extraction is attempted. Frequent insertion of the small magnet into the vitreous in the hope of finding the metal injures the eye and renders later attempts at extraction difficult, while the employment of the large magnet is not without danger when the position of the body is not known. 3. Early extraction offers the best chance of saving the eye. When the track of the body is through the cornea and lens, its position in the vitreous will indicate whether less damage will be done by removing the metal through the open entrance wound or through a new opening in

the sclera close to the indicated position of the body. 4. The more extended use in the future of the larger magnet in cases of steel in the vitreous chamber to draw the metal to an opening in the sclera, after its position has been accurately determined, will probably achieve better visual results than have been obtained in the past with the small magnet introduced in the vitreous. 5. Iron or steel which has remained in the eyeball until a fibro-cellular covering envelops it can not be dislodged with the magnet. Extraction with forceps, and the employment of normal salt solution to replace any vitreous lost, has resulted in several instances in eyeballs of good cosmetic appearance, and is an operation worthy of trial. Forceps extraction must also be employed when the body is of copper or glass. 6. Extraction is a safe operation, and under proper precautions is free from the dangers of panophthalmitis or meningitis." A tabulated summary of the cases is given.

18. **X-Ray Precancerous Keratosis.**—The conditions described by Johnston differ decidedly from x-ray burns, and must be classed, he thinks, as precancerous keratosis. Two cases are reported showing the conditions. There was no tissue lost, but the skin of the exposed part became red, thickened, and hard as in scleroderma, with excruciating boring pains. He thinks it is out of the question to leave these cornifications, as they are potentially malignant. He would excise them thoroughly and repair by grafting. Both cases were in x-ray workers, one a surgeon, and the possibility of irritation from developing and toning liquids is suggested, but Johnston remarks that he has examined the hands of a number of photographers and seen nothing approaching to this condition.

19. **X-Ray Treatment of Skin Cancer and Sycosis.**—The paper of Rinehart is written with special reference to the recognition of the x-ray in the treatment of skin cancer and non-parasitical sycosis. There is no pain in the treatment, little scar left and the possibility of more thorough eradication of the disease. He thinks that there must be more than the inflammation produced by the light and suggests the possibility of something in the nature of electrolysis destroying the cancer cells and the hair follicles.

20. **X-Ray and Calculous Nephritis.**—Of 206 cases examined on account of the suspicion of calculus, Leonard detected calculi in 65. Contrary to previous opinion the ureteral calculi were more frequent than the renal, which shows the greater accuracy of the method. In only one case in which a negative diagnosis was rendered was calculus found on operation and this mistake was due to defective technique in placing the plate, the shadow of the calculus being cast outside it. In three other cases of negative diagnosis the patient subsequently passed small calculi, the error being made in reading the negative. The percentage of error so far in the negative diagnosis has been less than 2 per cent. The results compare favorably with other methods of diagnosis and it should be noted that the calculi overlooked were all so small that they subsequently passed. There is no inconvenience to the patient to speak of, or pain, or any danger of infection by the introduction of instruments and yet the results of examination are more comprehensive than those obtained by any other method. Another advantage is the rational treatment of the patient by purely medical, dietetic and hygienic methods when the absence of calculi is determined by this means, and the value of the positive diagnosis is shown by the accuracy and completeness of the results of operation.

21. **Fractures of the Femur.**—Hibbs recommends the long traction hip splint, such as is in use in hip-joint disease, as the best treatment for fractures of the upper third of the femur. He illustrates the method of its employment and reports a case. He has since treated two other cases with similar splints with like satisfactory results. With this instrument the tendency of the upper fragment to tilt forward in fractures of the upper third of the femur ceases to be difficult to manage, and the treatment should be as successful as when the fracture occurs at a point lower down.

24. **Electric Ozonation.**—In the conclusion of his paper Curtis recommends electric ozonation to the consideration of

the profession for the following reasons: 1. The device is not complicated and the cost of the apparatus is not prohibitive, and its maintenance amounts to practically nothing. A nurse can be easily taught to operate the machine. 2. The high tension and the low ampère of the current eliminate all danger from the shock. 3. The high-tension current and the great quantities of ozone liberated are productive of rapid therapeutic results. 4. The efficiency of the machine is not impaired by damp weather, and it is, therefore, always ready for use. 5. The machine is portable and well adapted for use in the sick-room. 6. It generates pure ozone and for that reason it is superior to any oxygen apparatus. 7. Chronic and acute cases are alike amenable to the curative effect of electric ozonation. 8. This appliance is a valuable diagnostic aid.

26.—This article has appeared elsewhere. See THE JOURNAL of January 25, [147, p. 281.

27. **Creosotal.**—Experience with 18 cases treated in the Roosevelt Hospital from May 1 to November 1, 1901, almost exclusively with creosotal is reported by Thomson. Of these only one died. The cases averaged fairly as the average run of pneumonia cases, and two or three were decidedly severe. In the one fatal case the drug seems to have been ineffectual, for reasons which he does not explain. He thinks it is quite possible that this drug may exert a special effect on the course of pneumonia. It also seemed to effect very favorably the undesirable complication of tympanites. He has never noticed any depressing effect of it on the circulation, nor need there be any fear of its acting injuriously upon the kidneys, even if they were previously diseased. His success in these 18 cases is considerably above the average as regards the slight mortality. His usual formula for administering it is:

R. Creosot. carbonat. .... 3iv  
Glycerini ..... 3j  
Aq. menthæ ..... ad Oss  
M. Dose: Tablespoonful in water.

28. **Ringworm.**—Goose grease is the special treatment for ringworm recommended by Jackson. He says if we add a dram or more of the crystals of iodine to the ounce we will have a most effective treatment for ringworm. At the Vanderbilt Clinic at New York, this preparation has been extensively used for two or three years and almost exclusively after a few months' treatment. It should be applied twice daily until it has produced a reaction, as is shown by swelling of the patch, and then once a day is sufficient. In two or three weeks the hair falls out and the spot becomes bald, and when it grows again the patch is well. No epilation is necessary. There may be a little pain with the first application, but later even a child does not complain. He cautions, however, to use the genuine article, as there are some imitations on the market.

38. **New Wearing Apparel and Hygiene.**—Heidingsfeld calls attention to the effect of the use of new clothing which is made in sweat shops and used without previous washing and ironing. Frequently it has been stored away in some damp place under conditions favoring the development of the growth of any pathogenic germs that might exist. He reports several cases that have been observed and says he has often been called in to see members of clothing firms and employees who show marked evidences of herpes tonsurans acquired no doubt by handling finished products from so-called sweat shops. The laity should be disabused from the belief that everything new is clean and led to believe that everything new, if possible, should be washed and ironed. In this way we might eliminate many distressing forms of skin infection.

39. **Sympatheticotomy.**—Renaud finds this operation of value in obtaining the vaso-dilating effect required in the treatment of optic nerve atrophy and he reports cases where he has performed the operation with benefit. He thinks it of value only in cases where atrophy is beginning or is incomplete and before too pronounced structural changes have taken place. There must be considerable normal nerve tissue remaining. It is only necessary that the superior ganglion of the cervical sympathetic be removed, as it is from this ganglion alone that the sympathetic fibers to the eye and orbit are derived. He would also recommend its being removed on both sides and sug-

gests that the lack of success in glaucoma may sometimes be due to unilateral operation.

**54. Carcinoma Uteri in Pregnancy.**—The literature of the treatment of carcinoma complicating pregnancy is reviewed by Cumston, who sums up his conclusions as follows: If the carcinoma can be radically removed the life of the mother alone is to be considered. Up to the beginning of the sixth month of pregnancy vaginal hysterectomy is the operation of choice, but after this period abdominal hysterectomy, or Duehrssen's vaginal Cesarean section followed by hysterectomy is indicated. If the neoplasm is inoperable the life of the child must be considered, but if the progress of the growth is such that the mother becomes rapidly cachectic, thus compromising the fetal vitality, pregnancy should be interrupted. Palliative treatment alone should be instituted, because partial operations on the neoplasms usually produce hemorrhage, and do not materially benefit the mother. Cesarean section at term may be done, but leaving the uterus involves the danger of septicemia, consequently Porro's operation should be chosen if the peritoneal tissues are not so infiltrated as to render it dangerous.

**58. Intestinal Anastomosis.**—Allis' first operation here described was resorted to because of the lack of the Murphy button, which he formerly used. It was an end-to-end anastomosis, and he remarks that if the reader will divest himself of his coat and place the cuffs parallel he can look down into the sleeve ends as into a double-barrelled shotgun. The inner surfaces of the sleeves correspond to the mucous surfaces. Now if the two proximal edges of the coat are sewed together by a suture that passes entirely through them, fully one-half their circumference can be utilized. If now you will turn in the remaining portion you will find you can readily complete the circuit by sewing the outer surfaces. In this way he successfully approximated the intestines in the case. The fact that the mucous membrane can be safely included in a suture emboldened him to repeat the operation, and finding by experience that his fingers could not always accomplish the purpose he has added to his case two instruments that he has found very convenient, not only as special aids in anastomosis, but also in general surgical work. One of these he calls the tenaculum forceps, which he uses very much as women use pins and basting thread to secure their work temporarily. It does not matter what stitch is used; all that is essential is that the approximated bowels should be securely united. Having firmly approximated one-half the circumference, he removes the forceps, and, turning the partly united sutures half around he seizes the same with the tenaculum forceps, and with a pair basting the work a little further on, the through-and-through suture can be continued almost entirely around the entire circumference. When near the ends of the approximation he finds the tooth forceps with serrations on the edge, convenient for turning in the mucous edges adjusting the serous, and holding them approximated until sutured. In the sewing of the serous surfaces any suture that is convenient will answer the purpose. The rule that only the serous coat must be pierced is no longer entertained, and the operator will act wisely if he penetrates the thickness of the intestinal wall. Whatever suture he employs, if he makes them fairly near together he finds they will be buried as he tightens them. In this way every possible intestinal anastomosis can be accomplished. He illustrates his paper with schematic drawings of the different stages of the operation as well as further theorizing the gastro-intestinal anastomosis performed in the same manner. Three cases are reported by Dr. McReynolds in which Allis' method was employed with success.

61.—See abstract in *THE JOURNAL*, xxxvii, p. 858.

**65. Iodoform and Carbolic Acid Intoxication.**—Stone has noticed that certain patients have a peculiar susceptibility to these substances and that their use is not without danger. He believes that iodoform can be dispensed with in most cases, at least by obstetricians, gynecologists, and abdominal surgeons to advantage. He notices the bad effects that sometimes occur in apparently producing visceral troubles, such as nephritis, adhesions, etc., as indicated by experiments on animals. He calls attention in conclusion to a peculiar effect of carbolic

acid taken internally, namely, the rapid overcoming of the patient by the drug so that the effect is much like that produced by some cerebral or cerebrospinal intoxicant. It is certain that its action is not merely that of a caustic, having a local effect only. In the two cases where it was used this effect was marked, and he believes that the rapid absorption of the drug from the rough surfaces of the endometrium has the same effect as that produced by its internal administration.

72.—See abstract in *THE JOURNAL*, xxxvii, p. 934.

**73. Manual Stigmata of the Hand.**—The special features to which Courtney calls attention are stub-thumb or abbreviation and clubbing of the phalanx of the thumb, shortening of the little finger, and infantile nails. These he thinks are often found in persons of neurotic temperament liable to hysteria, hypochondria and to become the victims of morphin or alcohol.

**44. Sexual Inversion.**—Seligmann's article gives some interesting observations of the modes and habits of certain native races, more especially those of New Guinea and Borneo.

77. **The Czolgosz Case.**—See editorial, January 25, p. 252.

**78. The Czolgosz Case.**—Drahms discusses the peculiarities of Czolgosz and points out what he thinks are stigmata indicating degeneracy. He prophesies that at the postmortem will be found unduly thickened cranium, excess of Wormian bones and possibly imperfectly closed sutures, a pyramidal skull, light brain with few and shallow convolutions and the existence of confluent fissures.

**79. Consciousness.**—Kiernan criticises Barker for ignoring the former articles of Hammond which advocated the co-existence of consciousness throughout the whole extent of the nervous system.

**80. Eddyism.**—Paquin reviews some of Mrs. Eddy's statements, showing her up in quite an interesting way. He believes that christian science advocates immorality and crime by teaching that sin does not exist and directly threatens public welfare.

**83. Inversion of the Uterus.**—Cushing believes that the Thomas operation of laparotomy and dilating the funnel is, with the Trendelenburg position, the operation of choice in old cases of uterine inversion. It is here safer, surer and more surgically satisfactory than any other operation.

84.—See abstract in *THE JOURNAL* of January 11, p. 125.

**88. Prostatic Massage.**—This procedure is adaptable, according to Schmidt, in 1: Where we are treating inflammatory infarctions or congestions, where massage should be applied to hasten this absorption by stimulating the circulation. 2. In cases where it is desired to express out the fluid contents, especially in pathologic cavities. 3. Where endeavor is made to produce normal development of the undeveloped prostatic sphincter. 4. In cases of impotence, due to loss of the prostatic function where infection has not occurred, but exhaustion has set in, following excesses. In general neuroses of the prostate it is necessary to be cautious in the application of massage. The organ is exceedingly sensitive and the condition of the patient frequently changes for the worse. The technique is specially mentioned. All unnecessary pain on the introduction of the oiled finger should be avoided, and gentleness in all particulars should be the rule. The patient must be either in the knee-chest position or a standing one. The author does not believe in the frequent necessity of apparatus for the elongation of the finger as the loss of a tactile guide is objectionable. Nevertheless in certain cases it may be of use.

96.—See abstract in *THE JOURNAL*, xxxvii, p. 995.

100.—*Ibid.*, p. 996.

101.—*Ibid.*, p. 997.

110.—*Ibid.*, p. 327.

**111. The Czolgosz Case.**—Christison's article reviews the subject of epilepsy, maintaining that epilepsy is lunacy pro tem and applies his views to the assassin Czolgosz, claiming that the facts indicate that Czolgosz was a case of the borderland lunatic type.

**114. Mydriatics.**—The design of Risley's article is primarily to discuss the motive for the employment of mydriatics and to

give instances to show the necessity for their use in a very large percentage of cases of asthenopia. He thinks that the opinion that it is not necessary to use these drugs in every case requiring glasses is in accord with the general impression, but that they are required in many cases for their satisfactory and successful treatment is also the experience with the majority of his colleagues. He reports cases of asthenopia and remarks that in cases where there are no fundus changes or morbid anomalies of binocular vision homatropin and duboisin may be and often should be employed. But in cases such as some of the examples given the longer duration of the cycloplegic is an important therapeutic factor, not to mention the greater anesthetic action of atropin and hyoseyamin as compared for example to duboisin.

**115. Vicarious Fovea.**—Two cases of operated strabismus are reported by Davis which indicate to him that in some cases at least the new formed macula has not only the same acuity of vision as the normal macula, but also, like it when stimulated, assists in the most perfect associated ocular movements.

**116. Fitting of Glasses.**—Burnett notices the methods employed for the additional examination of ametropia, and remarks that even when we have used all the data the ophthalmoscope, ophthalmometer, and the shadow test have furnished our real trouble seems often to have only begun. The personal equation of the patient as well as of the observer must be considered. In the eye we are not dealing with an optical instrument only, but a sense organ in which judgment must give expression to the impression received. Then we have the erratic action of accommodation to deal with and the irregular refraction outside the visual zone in the area hitherto covered by the iris. He has found that the difference between the refraction at the nasal and temporal sides of the cornea amounted in some instances to 3 or 4 D. There is nothing left but a patient and painstaking work with the trial case, having in mind always an ideal refractive condition based upon the knowledge obtained by all the objective methods of examination, to which we should endeavor to attain through the sense of the patient. In this time is a most important factor. A number of seances are often required, and then it may be necessary to order glasses for a period of experimentation which can be obtained in no other way. Of the various means that have been devised all are useful, but the great demand is for tact in handling people, quickness in seizing suggestions, and infinite forbearance and untiring patience on the part of the examiner. He is most successful with his refraction cases who possesses these qualities in the highest degree.

**118. Climate or Spectacles?**—Among the various individuals who seek relief in Southern California there are not a few nervous wrecks who find little relief until they have fallen into the hands of the oculist. Hull would suggest to every physician who advises patients to try that climate to ask them whether they have had their eyes examined by a competent oculist. Some would not come, they would find spectacles cheaper. He reports several cases illustrating his views. He thinks it would also be well to examine the eyes of every person having consumption and kindred exhaustive conditions, with the view of correcting any error of refraction, or heterophoria, which could cause reflex trouble.

**121. Tuberculosis.**—Lane has reviewed the health statistics and discusses the relative rôles of heredity and infection in this disease. He agrees with modern opinion that the disease is not usually transmitted directly, but hereditary predisposition offers a favorable soil for its development. He believes that the disease should be a notifiable one, but that we should not consider the consumptive who takes care of himself as a dangerous individual or at an objectionable to immediately associate with. We should avoid exaggerating the contagious nature of tuberculosis and adding unnecessary hardships to the consumptive's lot.

**124. Laryngeal Tuberculosis.**—Curtis describes the principal features of laryngeal tuberculosis and discusses the question as to whether it is primary or secondary, concluding that the former type has been pretty well disposed of for lack

of clinical evidence. It has been his experience that autoinfection of the larynx occurs in recently-infected cases, possibly before the toxins have rendered the larynx less prone to autoinfection by the bacilli in the sputum. That the pharyngeal lymphatic ring may be the seat of the disorder and culture ground is abundantly proven. He remarks that in several of his own cases the early symptoms were obscure. The physical signs were lacking except that the vocal cords were sluggish in response to vibratory movement and the morning temperature of the patient was below normal. He calls attention to the fact that the pulmonary signs may be negative and only a slight afternoon temperature exist. We must watch carefully for the sub-mucous yellowish-gray spots which sooner or later appear beneath the translucent membranes in the laryngeal region and the aryepiglottic folds. In the early diagnosed cases we must prevent the results by local treatment, such as the injection of guaiacol and carbolic acid into the tissues. A simple persistent congestion of one cord with a slightly swollen appearance is another indication of the possibility of early tuberculous infection. He ends by remarking on the importance of studying these initial evidences while a possibility of averting the disease still exists.

**127. Tinnitus Aurium.**—The following is Kerrison's recapitulation: "In our search for the cause, we have the following sources of information to draw from: 1. Evidences of disease in any portion of the conducting apparatus as shown by physical examination. 2. History of the case, and character of the sound, as described by the patient. 3. Results elicited by careful functional examination. 4. Evidences of disease in other parts of the body, particularly as to the presence of digestive disorders, circulatory disturbances, blood dyscrasias or disease of the nervous system. 5. Effect of certain drugs, either in relieving or aggravating the tinnitus. The importance of a careful physical examination of the ear becomes evident from the fact that any appreciable lesion in any portion of the conducting apparatus must act at least as a contributing cause in the production of tinnitus, whatever the character of the sound and whatever the chief factor in its causation may be. From the patient is learned the character of the noise—whether unilateral or bilateral, simple or elaborated, constant or intermittent, pulsating or uniform, of high or low pitch. The importance of the pitch depends upon the fact that, generally speaking, low sounds suggest tympanic and high sounds labyrinthine involvement. The pitch is best determined by holding a vibrating tuning-fork of 256 D. V. opposite the patient's ear and requiring him to decide whether the subjective noise is higher or lower in the musical scale, according to which it may be classed as a high or low sound. Further than this, the determination of the exact pitch has not been demonstrated to be of any practical value. It is also of importance to learn whether the noise varies in intensity, at what hour it is most noticeable, how it is influenced by physical exercise, rest, ingestion of a full meal, etc., etc. The length of time during which the tinnitus has been present is also of some importance, since tinnitus of purely tympanic origin rarely persists very long; while a subjective noise persisting constantly from childhood to adult life might suggest the possibility of anomalies in the course or position of vessels, etc., etc. Of still greater diagnostic value are the reactions to functional tests. Thus elevation of the lower tone limit suggests tympanic disease, whereas lowering of the upper tone limit points to labyrinthine disturbances. Bone condition is also of diagnostic value, increase pointing to tympanic, and diminution to labyrinthine disorder. With tinnitus confined to one ear, Weber's test, if lateralized to the same side, would suggest tympanic trouble; whereas if lateralized to the opposite side, the inference would be of labyrinthine disturbance. In other words, the same tests which would aid in locating the cause of an impairment of hearing may be used in our search for the lesion upon which tinnitus depends. But while the physical and functional examinations of the ear may give clear enough indications in tinnitus of purely aural origin, there are also many cases in which they are of service only in their negative results, which direct the attention away from the ear in the search for the

underlying cause. In such cases the most thorough physical examination and most searching inquiry into the patient's general condition may be necessary—all the organs of the body being looked to for evidences of disease, and each slightest symptom being weighed as a possible factor in producing the patient's trouble. Obviously, no single plan of treatment will ever be found applicable to all the different forms of tinnitus and the results of treatment must always be proportionate to the thoroughness of the search for the underlying cause."

**131. Internal Derangements of the Knee-Joint.**—Allison summarizes his paper by saying that: "1. The internal derangement of the knee-joint should suggest: (a) Dislocated semilunar cartilage; (b) the impingement of a fold of synovial membrane between the ends of the bones; (c) presence of a floating cartilage or joint mouse; (d) contusion of the margin of the semilunar cartilage, with swelling and infiltration of blood at the site of their attachments. 2. These conditions can usually be differentiated. 3. The treatment is rest, massage, mechanical support, gymnastics, and operative. 4. The operation should not be undertaken without carefully analyzing the case, and usually only when the other measures have failed."

**132. Dental Affections and the Eye.**—The influence of diseased teeth upon the eye forms the subject of Bicknell's paper. He notices first the infectious disorders which travel upward to the orbit by a continuity of tissue and reports two cases of orbital abscess from this cause. Neuroses are considered under the following heads: reflex irritation affecting the striated and unstriated muscles; reflex irritation affecting the mucous membrane; reflex irritation affecting the retina, optic nerve, and intraocular tissues. Each of these with their subdivisions are remarked upon. The literature, of course, is large, since almost everything has been attributed to teething.

**135. Formalin.**—Anderson calls attention to the use of formalin in certain local excrescences, which he classes under the head of semi-malignant, as they have the general appearance of a malignant growth. He also remarks that rectal fissures and fistulas are sometimes cured by this local application, and also suppurating surfaces to which it can be even more quickly applied. Sinuses wherever found can generally be made to close by this agent.

**139. Bromid of Strontium.**—Dearing has found this bromid most effective in an average of 40 cases of epilepsy treated daily in hospital practice. He also gives the results of 60 cases that he treated daily for a period of 130 days with bromid of strontium alone, which record shows a very remarkable reduction in the number and vigor of the convulsions, while there was no depression either mental or physical, or loss of appetite, no acne or untoward symptoms of any kind. Each case, however, must have individual attention, the bowels kept regular, the secretions, excretions and habits attended to. The dose he uses is from 10 to 30 grains, preferably in a solution with a bitter tonic.

**144. Children's Testimony.**—Pettyjohn finds that children are not reliable witnesses. He reviews some legal opinions and gives facts derived from officers connected with the trials of cases. He thinks that the testimony of children and infants is in most cases unreliable, and that children should never be called as witnesses except under the most favorable conditions for the child, and never in an open court. There should be expert opinion as to whether such testimony is admissible and it should not be allowed to stand against the accused except when the court is thoroughly satisfied as to the child's intelligence.

**152. The Future of the Negro.**—This article gives a number of interesting statistical details and the author's conclusions therefrom. He believes that the negro race is dying out, that its death-rate is exceeding its natural increase, and that the negro question will sooner or later become one of the past. The insanitary habits of the mass of the negro race and their immorality are gradually killing off the race. He does not exclude, however, in his arguments the possibility of the few exceptional cases continuing to survive and propagate a better race, a possibility which it seems should be considered. The article is written in a kindly spirit toward the negro, and he

advocates the study of his traits and tendencies and, if possible, the rescue of him from the disease and immorality which threaten to destroy him.

**154. Tornwaldt's Disease.**—This condition of chronic nasopharyngeal bursitis is accepted as an actual entity, or at least a clinical syndrome, by Roy. Whether the so-called bursa pharyngea is a distinct bursa or blind pouch, he says it is certainly the cause of a peculiar form of nasopharyngeal catarrh. He does not agree with Delavan in saying that it is nothing more than a neglected hypertrophy. Two cases are reported in neither of which was the treatment satisfactory.

**159. Febris Innominata.**—Preston calls attention to certain cases in which the clinical signs of typhoid were lacking except the continued fever which, however, lacked the cyclic character of typhoid. None of the cases had diarrhea, tympanitis, rose spots, nor delirium to any great amount, nervousness nor the typhoid tongue. The suspicion of malaria seemed to have governed the treatment to a large extent, but without specially striking success. He thinks it possible that we have a toxic cause for some of our cases of continued fever not yet explained, and that we have passing under the name of continued fever conditions that are not true typhoid. The blood test he thinks will come into play to determine the diagnosis, though more than the Widal test alone will be required.

**164. Acute Hemorrhagic Nephritis.**—Miller reports the case of a child thirteen months old in which this condition occurred and reviews the literature, giving an analysis of the symptoms and summary of the reported cases. He concludes that nephritis is a rare complication of influenza occurring chiefly in young adults and children, and is almost unknown in infancy. Albuminuria is more frequent, probably present in all severe cases. Hematuria alone is not infrequent and is seen most often in early life. Nephritis may appear early in influenza or after the acute symptoms have subsided. It is usually an early complication, occurring in one half the cases before the eighth and in two-thirds of the cases before the twenty-first day after the commencement of the influenzal attack. The type varies. It may be that of ordinary acute nephritis, but the majority are of the hemorrhagic type, this being specially frequent in young people and children. Edema is absent in more than one-half the cases, and when present is apt to be slight. The onset is usually attended with fever. The nephritis is of short duration, generally lasting under three weeks. The prognosis is good, though few cases pass into the chronic subacute stage. If the kidneys are already affected the outcome is worse and apt to be serious and fatal. From the meager pathological reports the lesions appear to be those of infectious or toxic nephritis, often taking the form of glomerulo-nephritis.

**168. Tuberculosis.**—Crandall summarizes his views as to the malnutrition of tuberculosis in the following: "1. Wasting, anemia, and other evidences of malnutrition are constant accompaniments of tuberculosis in children. 2. These symptoms may occur in infants long before local disease can be detected and occasionally no local signs whatever are manifest before death. 3. In infants, tuberculosis shows a special tendency to be disseminated or to conceal itself in the deep tissues, as the lymph nodes. The disease may then run a course identical with simple marasmus. 4. In some cases a period of anemia and wasting is followed by a stage of irregular fever, after which local lesions appear, usually in the lungs. 5. In other cases tuberculosis in children begins with well-marked local manifestations, particularly pneumonia. In these, evidences of malnutrition appear promptly and are usually progressive. 6. The anemia of tuberculosis, whether it appears before or after the occurrence of other symptoms, is usually a simple anemia and presents nothing characteristic. 7. A diagnosis of tuberculosis cannot be made alone from the character of the anemia or the malnutrition. However, persistent and increasing malnutrition in a child without discoverable cause is always suggestive of tuberculosis. 8. Anemia in adolescents should receive prompt and active attention, for it vastly increases the danger of tubercular invasion, which is particularly common at that period of life."

2. **Latent Syphilitic Aortitis and Visceral Neuralgia.**—Rénon states that the intense visceral pains in the case described caused the diagnosis of liver or kidney colic accompanied by aortic insufficiency to be made. The aortic lesion had developed in the course of a year and suggested a possible explanation for the visceral neuralgia. The pains began to subside after ten days of specific treatment and all symptoms vanished before the course was completed. There was a history of mild syphilitic infection twenty years before.

3. **Early Diagnosis in Relapse in Typhoid Fever.**—Lemoine calls attention to the dissociation between the pulse and the normal temperature in case of convalescence from typhoid fever when a relapse is impending. He gives the curves of a number of cases showing the rapidity of the pulse with the low temperature.

5. **Information to be Derived from the Urine in Nutritional Diseases.**—Among the various valuable points to be learned from study of the urine, which Robin enumerates, is the early differentiation of typhoid fever. The latter is probable, 1, when the urine is the color of beef bouillon with greenish reflections, turbid but without the urobilinuric tint; 2, when there is slight, constant albuminuria; 3, when urohematin and the derivatives of skatol disappear; 4, the constant presence of indican; 5, increase of uric acid; 6, absence of uro-erythrin and 7, marked decrease in the earthy phosphates. In dubious cases a considerable amount of earthy phosphates, without albumin or indican, testifies against typhoid fever. In case of icterus from liver colic, if the urine ceases to turn green when nitric acid is added, the presumption is that the bile is resuming its natural course. In case of pneumonia or other similar disease, an increase in the amount of urine and sudden increase in the proportion of solid matters herald the crisis and deference close at hand. In the treatment of obesity, it is possible to estimate and maintain the balance between the nitrogen ingested and the amount excreted. In a recent case Robin had reduced the patient's weight by 27 kilograms, carefully maintaining the nitrogenous balance. When this point was reached he found that the excreted nitrogen surpassed the amount ingested, demonstrating that urea was being formed at the expense of the muscles. The patient had lost all the fat he could lose, and it was time to suspend the reducing treatment. In diabetes also, the urine will show whether antipyrin is being tolerated or not. If the density of the urine increases, even although the proportion of sugar is diminishing, the drug should be discontinued.

9. **Surgical Intervention in Case of Cirrhosis of the Liver.**—Guillot describes a case in which Talma's operation was successfully performed. He states that this operation has been done 28 times to date. There is no record of the results in the case of one patient; 2 were improved and 11 were cured. It failed in 14.

12. **Trunecek's Inorganic Serum Treatment for Arteriosclerosis.**—Lévi publishes a number of cases of various affections attended by arteriosclerosis, which he has treated by injections of Trunecek's mixture of all the alkaline salts normally in the blood serum, which he calls "inorganic serum." It is ten times more concentrated than natural serum. (See THE JOURNAL, xxxvi, p. 1507.) In one case the patient was a woman of 57 with aortic stenosis and insufficiency and ectasia of the right primary carotid. For twenty months she had suffered from nocturnal attacks of pain simulating angina pectoris, lasting sometimes two and one-half hours, and recurring nearly every night. These attacks were completely banished by a few injections of the serum, but it had no effect on the anatomic lesions. The dyspnea of arteriosclerotic subjects is cured by a very small amount of the serum. Relief is usually experienced even after a single injection. Lévi de-

scribes 5 cases in detail. In a case of arterial cachexia in a man of 86, the attacks of asthma ceased, the dyspnea was relieved, the cyanosis disappeared, sleep, appetite and physiologic warmth returned, with general physical and moral improvement. An ulcerative lesion was not affected, but this also yielded in a similar case in Trunecek's experience. Lévi has been making a special study of the effects of the serum in cerebral arteriosclerosis. He found it very effective in the cure of localized symptoms, vertigo, visual disturbances, tinnitus aurium, headache and deficient memory, even in old established cases. Tests with other patients showed that it was ineffectual in case of an actual focus of necrosis. He applied it also in 22 cases of sclerous otitis. All were improved, some so rapidly that after a single injection the patients could hear sounds which they had not been able to hear for years. He is now studying the action of the serum in rheumatism, nervous affections, etc., and various conditions of congestion, in which it promises well. The formula of the serum is as follows: Sodium sulphate, 44 cg.; sodium chlorid, 4.92 gm.; sodium phosphate, 15 cg.; sodium carbonate, 21 cg.; potassium sulphate, 40 cg.; aq. dest. to make 100 gm. The amount injected is progressively increased from 1 c.c. to 5, the injection repeated every second, fourth or seventh day. Trunecek prefers the forearm, but Lévi makes the injection in the buttocks. He also alternates rectal with subcutaneous injections, ten of each, in some cases. He states that a rectal injection of 35 c.c. causes no disturbances. The action of the serum is rapid but transient. (See below.)

**16. Study of the Action of Trunecek's Serum.**—Lévi is convinced that Trunecek's concentrated serum has a multiple action. He has demonstrated that it lowers the blood pressure and modifies the composition of the blood to a certain extent. This latter feature explains the benefit derived from it in chronic rheumatism, in the symptoms which sometimes accompany neurasthenia on a foundation of arteriosclerosis, in hysteria, in local congestions, etc. He relates a number of cases in which this serum has proved remarkably effective in curing retention in incipient prostatitis, hysteric sweats and nervous pseudo-rheumatic pains. It is applicable to all cases of arterial hypertension, all forms of arteriosclerosis, sclerosis of the vessels of the heart, brain, ear and kidneys. Its efficacy is more pronounced the earlier it is administered, before the vessels have lost their contractility. Established lesions are no contra-indication, but its action is less evident. It may prove effective in averting or attenuating seizures in epilepsy, eclampsia, in certain cases of uremia and even of diabetes. He is now testing a large number of artificial serums of this kind and mineral and sea water, to see if still better results are attainable.

**17. Enteroptosis, Movable Kidney and Neurasthenia.**—Glénard has been studying for fifteen years the variety of nervous dyspepsia or vague neuropathy which proves rebellious to ordinary treatment. The clinical picture is much the same as in the curable cases, although perhaps symptoms of insufficiency of the liver or cholemia are more pronounced. If the patient reclines, with the lumbar region elevated, and sighs profoundly it is possible to palpate the kidney under the right hypochondrium, with other indications of general enteroptosis. The latter is the primary trouble. It usually commences at the angle of the colon and may be traumatic and primary, or secondary to infectious or toxic processes or to emotions. As the intestines settle down, the kidney is dragged with them, the liver is also affected, and the gastric digestion suffers. The fundamental characteristics of this condition, encountered in all stages, are a sensation of weakness, discomfort in the mesogastrium, attaining its maximum two or three hours after dinner, aggravated by fats, starches, raw foods, wine and milk, with constipation and insomnia during the middle of the night. The abdomen is relaxed, the cecum can be palpated as a small, hard roll, the transverse colon as a cord across the aorta, which is easily accessible to palpation. Treatment should be fourfold: an elastic abdominal bandage; daily saline laxatives, 7 gm. of sodium sulphate and eventually 5 to 10 cg. of aloes; a meat

diet; sodium bicarbonate and in case of paroxysmal attacks, treatment as for biliary lithiasis, although calculi rarely occur. Cold hydrotherapy is a valuable and certain adjuvant. The movable kidney is merely an incident in the general ptosis, and symptoms referred to the kidney are much more liable to be the result of the intestinal displacement, as is also the case in troubles caused by deformity or abnormal mobility of the spleen, liver or kidney and dilatation of the stomach.

**19. Tuberculosis of the Larynx in Children.**—Perrin's monograph was awarded the Heydenreich prize by the medical faculty of the University at Nancy. He reviews all the cases published in European literature and adds two new case-reports. One of the latter patients—a girl of 6—recovered complete health under medical treatment. Not a trace of tuberculous disease could be discovered nine months after treatment was instituted. It consisted in administration of potassium bromid, hot packs to the neck and thorax and medicinal sprays. Cases of recovery are rare.

**20. Inguino-Interstitial Hernia.**—Berger has operated on seven men on account of congenital interstitial hernia complicated by ectopia of the testicle. The hernia spreads in the thickness of the abdominal wall by separating its layers. It may be exclusively intraparietal or there may be a diverticulum emerging through the external abdominal ring, which may also allow the passage of the testicle. The deep abdominal ring is higher and nearer the anterior-superior iliac spine than normally. The testicle in the hernial sac is almost always undeveloped, and the muscular and fibrous walls of the abdomen usually display marked atrophy and weakness. The spermatic cord is frequently too short to allow the testicle to be drawn to the scrotum. In some cases the testicle is entirely enclosed by a sheath distinct from the peritoneo-vaginal sac occupied by the hernia. In a few rare cases the testicle completes its descent and a parietal and scrotal hernia develops behind it. Inguino-interstitial hernia occurs also in women—he describes eight cases he has personally observed. This condition should be operated even in the aged, unless there are direct contra-indications, as serious accidents are apt to occur, and as it can not be effectively maintained by a truss. The incision should be parallel with the fibers of the external oblique, above Poupart's ligament. The testicle should be ablated if the subject is over 25, except in conditions peculiarly favorable for orchidopexy. Under this age every effort should be made to retain it. The strengthening of the abdominal wall is the most important part of the operation. If the Bassini method does not promise a certain result, the suture of the internal oblique and of the tendon of Poupart's ligament must be reinforced by incising the aponeurosis of the rectus and fastening the outer lip of this incision to Poupart's ligament throughout the entire extent of the inguinal canal. The operation is terminated by the superposing of the two lips of the incision in the aponeurosis of the external oblique and suturing its lower lip to the inner edge of the aponeurosis of the rectus, and its upper lip to the anterior surface of the aponeurosis of the external oblique, close to Poupart's ligament. Four cuts in the article show the various steps of the operation.

**22. Serous Meningitis Cured by Trephining.**—Lecéne describes a personal case and summarizes six others that have been published in which the symptoms indicated a serous meningitis. By this he means a very serious syndrome occurring in the course of acute otorrhea or otitis, suggesting brain abscess or meningitis. It is characterized by an evident hypertension of the cerebrospinal fluid, with cerebral edema. Lumbar puncture might cure in such cases, but the violent onset of the symptoms justifies more radical measures, and in the case reported bilateral trephining, allowing the escape of about 20 and 15 c.c. of cerebrospinal fluid, cured the patient completely. He was a young man convalescing from typhoid fever, and for three hours and a half had had a general convulsion every five minutes, with other serious symptoms. The convulsions continued unmodified until the second trephining opening had been made, when after the escape of 15 c.c. of cerebrospinal fluid, they ceased at once and did not recur. In all the seven cases the

trephining was undertaken for the search of a hypothetical abscess, and the exploratory operation proved the unexpected cure of a serous meningitis. Patients exhibiting this syndrome should not be allowed to die under the diagnosis of uremia or meningitis without radical intervention to allow the escape of the accumulated cerebrospinal fluid. One of the patients was not operated on, and the autopsy showed merely an accumulation of six ounces of fluid at the base of the brain, accompanying bilateral suppuration of the mastoid cells.

**23. Treatment of Traumatism of the Liver.**—Mercade adds two more to the limited number of successfully operated cases of traumatism of the liver on record. One was a stab wound, treated by rapidly suturing the lips of the wound together. The other was a contusion, resulting from the subject having been run over. It was impossible to coaptate the ragged lips of the wound and the suture merely aimed to draw the liver together in order to aid in cicatrization. Hemostasis was secured by supplementary tamponing. The wound was drained in each case and artificial serum injected.

**24. Neuropathic Accidents of Digestion.**—Féré describes 8 cases of unusual morbid manifestations accompanying digestion. In one case a previously healthy man had syncope after every hearty meal, and the same occurred in a patient with paralysis agitans. In a case of uncontrollable vomiting of pregnancy, numerous pains occurred during digestion. In another patient with neurasthenia resulting from a sunstroke, recurring pain was noted during digestion, located invariably in a traumatic wound in the leg which had healed perfectly and been free from symptoms for twenty-six years. There was no pain at any other time. In the fifth case, acroparesthesia and inability to walk occurred during difficult digestion in a woman with neurasthenic tendencies. In the sixth, difficult digestion was accompanied by aggressive actions and once by transient furious delirium, the attacks terminating in vomiting. A child exhibited a specific contraction of the left leg during indigestion, never noted at other times and subsiding always after she had vomited. The eighth patient was a general paralytic and difficult digestion was accompanied by profuse local sweats. Tardy and persisting digestive occurrences of this nature are probably due to intoxication, but the early and acute manifestations, terminating in vomiting or sudden defecation, are probably of reflex origin.

**25. New Explanation of Etiology of Tuberculosis.**—Ferran is director of the municipal laboratory of bacteriology at Barcelona, Spain. He announces that his researches have shown the tubercle bacillus to be merely a modified colon bacillus. Before the tubercle bacillus appears in the sputa, he finds constantly another bacillus which he calls the "phthiseogenic." This heralds the approach of tuberculosis, and tubercle bacilli soon appear. In his experiments with the colon bacillus, he found that under certain conditions this bacillus was substituted by the phthiseogenic bacillus and this in turn by the tubercle bacillus, although the conditions absolutely prohibited the possibility of extraneous infection. He believes that practicable vaccination against tuberculosis will soon be possible by following these indications. He has isolated the phthiseogenic bacillus from human sputa and from the excreta of dogs, and both bacilli finally turned into the Koch bacillus. Both induce cachexia after a preliminary pretuberculous pneumonia or other affection of the respiratory passages, and both are essential for the development of tuberculosis. The latter is merely a colon bacillosis, the bacilli modified by the chemical changes which it induces in the infected tissues. He has obtained the same clinical and experimental results with colon bacilli from man and from the cat. These bacilli grown in Martin bouillon or serum induce tuberculosis after being injected a certain number of times.

**27. Simple Nitropropiol Test for Sugar.**—Gebhardt has modified this test mentioned in THE JOURNAL, xxxvi, p. 354. He adds 10 to 15 drops of urine to 10 c.c. of water and dissolves one nitropropiol tablet in the fluid, warming it for two to four minutes. If there is any grape sugar in the urine, the fluid turns greenish and then a deep indigo blue. This reac-

tion does not occur with any other substances in the urine in the absence of sugar. The test is extremely simple, convenient and sensitive to even a small proportion of sugar.

**31. Ultimate Results of Operative Treatment of Retroflexion and Prolapse.**—Andersch tabulates the result of 304 operations performed at Pfannenstiel's clinic between 1896 and 1900 and 24 in his private practice. The total number of patients was about 750 in each. The remote results observed have confirmed him in the advantages of the following outline for treatment: If the displacement causes symptoms which require intervention, he treats with pessaries, as far as possible, all cases of movable retroflexion with or without prolapse or procidentia. All cases of movable retroflexion combined with prolapse or procidentia, and also all cases of prolapse or procidentia without retroflexion, are treated by vagino-fixation, with or without occlusion of the plica according to the age of the patient. The rare cases of isolated retroflexion of a movable uterus, unadapted for pessary treatment, are treated by ventro-fixation or the Alexander-Adams operation, and all cases of fixed retroflexion by ventrofixation.

**32. Liquid Air as a Disinfectant for Vagina and Uterus.**—Wolff and Meyer report that anthrax bacilli exposed to the action of liquid air for eight days were not killed, but their virulence was much attenuated. In eight series of tests on dogs, liquid air applied to the mucous membrane of the vagina and uterus, previously infected, caused the temperature to fall to normal, with other indications of a powerful disinfecting action.

**38. Etiology of Infectious Diseases from New Point of View.**—Menzel thinks that the state of the organism, the external conditions, etc., have a more important share in the etiology of infectious disease than has hitherto been appreciated. For instance, he suggests that the germ causing measles in children and the subsequent immunity may be merely the consequences of the peculiarly receptive state of the organism in childhood. It causes the clinical picture we call measles in the child, but in the adult it is possible that the same germ may be responsible for various catarrhs and bronchitis. He attributes the primary infection to invasion of the tonsils, and describes several cases of articular rheumatism commencing with sore throat, in which he was able to cultivate diplo- and strepto-cocci from the peritonsillar tissue, and staphylococci in a case of erythema nodosum. The etiology, therefore, of infectious diseases may be sought in the varying reciprocal relations between the human cellular economy and the ubiquitous micro-organisms under varying external conditions, such as climate, etc.

**41. To Reduce the Size of the Abdominal Cavity by Doubling the Abdominal Wall.**—Heidenhain reports and illustrates two cases in which he followed Piccolo's suggestion and reduced the size of the abdominal cavity after the removal of a large tumor. He incised the wall on the median line from the symphysis to the ensiform process, and doubled the walls over each other like a double-breasted coat. This procedure may also prove useful in abdominal hernias or enteroptosis.

**42. Acute Sepsis, Ileus, Iodoform Intoxication or Uncontrollable Vomiting, Which?**—Haeblerlin describes a case presenting the above puzzling clinical picture. The patient was a debilitated multipara in a new pregnancy. She owed her life to saline infusion, and made a rapid recovery after abortion had been induced. He suggests that possibly many of the operative fatalities are due to a combination of factors, harmless in themselves, such as vomiting and meteorism, but dangerous on account of the condition of debility, and producing symptoms such as we are accustomed to see only in dangerous affections of the peritoneum or violent mechanical disturbance of the intestines.

**46. Cold as a Cause of Arteriosclerosis and Joint Deformities.**—Von Manteuffel explains the tardy appearance of gangrene after a limb is frozen as merely the secondary, remote result of alteration or occlusion of the blood vessels caused by the cold. His research on limbs amputated on account of frost gangrene has confirmed this assumption, and also his success-

ful reproduction of the same condition by freezing the hind legs of guinea-pigs by spraying them with ether. The vessels exhibited the typical lesions of arteriosclerosis. The bones also suffered from the action of the cold, the manifestations being the same as in the vessels, that is, the death of the previous normal tissue and regeneration by connective tissue. As the bone dies, the periosteum probably begins to proliferate as cicatricial tissue, while in the epiphyses the defect is compensated by the bone marrow. The joint thus weakened yields to the pressure and an arthritis deformans may be the result, its development promoted by the weight of the body above. The alterations in the bones were so pronounced and direct that they were evidently directly traceable to the action of the cold rather than to the intermediation of arteriosclerosis. The edema in a frozen limb is not able alone to induce these processes of degeneration and regeneration, as he established by further experiments.

**47. Artificial Pneumothorax as a Preliminary to Operations on the Thorax.**—Delagénère has announced that a pneumothorax occurring during the course of an operation causes no trouble if it develops slowly. Doilinger thinks that the removal of extensive tumors of the thorax wall or in the lungs, would be much facilitated if pneumothorax were artificially induced the day before as a preliminary measure. He describes two cases showing the great benefit to be derived from this measure. In one a sarcoma the size of a man's fist was to be removed from the right wall of the thorax. The day before he inserted a tube in an incision in the fifth interspace under local anesthesia. The respiration was 35 to 40 a minute, the pulse 120, and the patient experienced no discomfort. When the thoracic cavity was opened for the extirpation of the tumor the lung was seen to be collapsed, but still sharing a little in the movements of respiration. The latter ceased for a few seconds when blood was wiped off the surface of the lung. The action of the heart continued normal all the time. The wound was sutured without disturbing the lung. It expanded completely in the course of two weeks. He had a similarly favorable experience in another case. The patient evidently stands the narcosis better when the pneumothorax is induced the day before and the operation can proceed more rapidly.

**48. Post-Typhoid Affections of the Bones.**—Langer reports two cases of an affection of the vertebrae involving also the spinal cord and emerging roots, evidently a post-typhoid spondylitis. Such post-typhoid ulcerations generally have a long incubation and frequently localize on a spot injured by some recent or old trauma. Quinke describes post-typhoid spondylitis as characterized by the unusual violence and extent of the spontaneous local pains, by the swelling of the soft parts, the acute, febrile course, rapid vanishing of the spinal symptoms, and the extremely frequent localization in the lumbar region. In one case the affection did not develop until seven years after the typhoid fever; in the cases described the intervals were four and eleven weeks. He has noticed that the agglutinating reaction is more often absent in the young than in adults and is soon lost. It was pronounced in one of his cases.

**49. Buttermilk for Infant Feeding.**—DeMattos states that since de Jaeger recommended buttermilk as a food for infants, six years ago, it has become universally and persistently popular throughout Holland. It has been tentatively introduced into Germany during the last year and has already won high appreciation. When pure, fresh buttermilk can not be obtained, families churn a little butter at home to provide the babe with its buttermilk every day. It is prepared by stirring a level tablespoonful—about 10 to 12 gm.—of fine rice, wheat or other flour into a liter of buttermilk less than twenty-four hours old. It is then boiled over a moderate fire until it boils up thrice, stirring continuously, after which two or three heaped tablespoonfuls of cane or beet sugar are added. Five years of extensive experience with this regime have confirmed its remarkable value in cases of children who are not thriving on breast milk or artificial foods and in desperate cases of all kinds.

**52. Clabbered Milk for Infants.**—Langstein reports twenty-five cases of very sick children who were fed on milk artificially clabbered with rennet, and then stirred or beaten to break up the clots very fine. In nearly every case the gastrointestinal symptoms rapidly subsided, the vomiting ceased and stools became normal. See *THE JOURNAL*, xxxvii, p. 480.

**55. Severe Anemia of Gastro-Intestinal Origin.**—Perutz points out that pernicious anemia is almost regularly accompanied by a lack of hydrochloric acid and of all the peptic ferments in the stomach, with diarrhea or constipation, and anatomic alterations in the alimentary canal. He describes a case in detail in which the symptoms indicated a serious blood disease and arsenic had been administered on the diagnosis of severe anemia. The patient had suffered from gastro-intestinal troubles for years and the arsenic only aggravated his condition. Perutz therefore treated the gastro-intestinal disturbances alone, by lavage of the stomach every morning and frequent irrigation of the intestines. The patient, a man of 53, was fed with gruel and egg, introduced through the stomach tube. Every evening a quart of chamomile tea was injected into the rectum. He rapidly recovered under this regime, gradually supplemented by more nourishing, easily digested foods, but the anatomic alterations in the alimentary canal still impose continued caution in the diet. His case had been considered hopeless by his previous medical attendants, but under this dietetic treatment he recovered strength and was restored to his business.

**56. Peculiar Emulsion Albuminuria in Eclampsia and Uremia.**—Cramer discovered in the case of three patients already in fatal coma that the urine was turbid and milky and did not become clear by repeated filtering. The microscope revealed that the emulsion consisted of albuminoids. It vanished spontaneously after the urine had stood two days in a warm room. Two of the patients were in puerperal eclampsia, the other in uremia, and the urine had been drawn on account of retention. This super-saturation of the urine with albumin probably indicates great insufficiency on the part of the kidney and speedy dissolution.

**57. Relations Between Diabetes Insipidus and Mellitus.**—Kuhn describes the case of a patient with diabetes insipidus. Eight days before her death, she presented the classical clinical picture of diabetes mellitus.

**60. Dietetic Treatment of Epilepsy.**—Schaefer had three epileptics under observation for a year and a half whose epilepsy dated from childhood and had proved rebellious to all treatment and entailed more or less imbecility. They had 20 to 30 seizures a month. He treated them from June 26 to August 10 by suppressing salt in their food and incorporating bromid in their bread, according to Balint's directions. (See *THE JOURNAL* of July 20, 1901, p. 228). The mental and moral improvement was marked and one patient had only 2 seizures during July, the second only 2 and the third 7, while none had any seizures during the last four weeks of the treatment. Return to ordinary diet was followed by the recurrence of the seizures after six to nine days. [Garbini reports similar experiences with 14 epileptics, in the *Revista Mensile di Neuropatologia* for December. The seizures diminished by 73 per cent. under suppression of salt and administration of 1 gm. of bromid a day, and the seizures were only a third as long. The mental and general condition showed marked improvement. All were severe cases. Lion has recently reported remarkable benefit in 21 cases of epilepsy from the simultaneous suppression of salt, administration of bromid and of brain extract.—Ed.]

**65. Advantages of Median Lithotomy.**—Miclescu reports that he has performed this operation 120 times in Macedonia and always with the most satisfactory results except in one case. The operation was always done in the patient's home, usually a shanty, without assistance. He ascribes his invariable success to the median operation, and to his practice of suturing the periprostatic and peri-urethral tissues with silk, never suturing the urethra itself. A catheter was introduced

into the fossa navicularis urethræ for three days. The wound healed usually in four days and the patients were able to get up the seventh. His single fatal case was a child. In this case during the course of the operation, the patient, operator and instruments were drenched by sudden rain through the roof.

**66. Indications for Operation in Case of Gastric Ulcer.**—Delachaux considers irrigating the stomach with a solution of iron chlorid the first indication except in case of perforation. Operative intervention is indicated only when perforation is certain, or when treatment with iron chlorid brings no relief and the certainty is thus acquired of the existence of stenosis or malignant degeneration.

**69. Treatment of Acute Catarrh.**—Nothnagel states that complete recovery after an acute catarrh is possible only when Nature's efforts at repair are not disturbed. It is therefore of the greatest importance to treat every acute catarrh, even the slightest, from the very first day, before permanent anatomic alterations occur, perpetuating the catarrh or entailing excessive vulnerability on the tissues. Old-established catarrh is practically incurable. Catarrh that has lasted six months is scarcely capable of complete retrogression. On the other hand, an acute catarrh will heal without medication if all injurious elements are kept away from it. These elements, in case of acute catarrh of the respiratory apparatus, are the breathing of cold or alternately cold and heated air, the action of vicissitudes of temperature on the skin, wind, dust, smoke and speaking. In case of catarrh of the digestive apparatus, food should be abstained from during the first few days as much as possible, and then for a long time the diet should be restricted to the foods making the least demands on the peptic and motor activity of the stomach and intestines. In both cases these precautions must be continued until the functional disturbances have entirely disappeared.

**71. Effects of Exposure to Cold.**—Lassar remarks that the effects of exposure to severe cold—freezing—like those of a burn, range from a mere patch of hyperemia to necrosis. Lupus erythematosus, for instance, develops as frequently in tissues that have been over-cooled as in those that have been overheated, in cabdrivers and field hands as frequently as in firemen and cooks. Cold affects the tissues less intensely at first, but its action is more persistent. The vascular system suffers most. The various pathologic processes which locate by preference at the tip of the nose are probably attracted by some preceding alteration in the blood vessels, due to the action of cold, possibly in remote childhood. Prophylaxis should guard against sudden exposure to severe cold and include rational hardening of the system against cold, as by the custom of a daily cold bath or rub. According to Lassar's experience, there is only one way of treating the permanent redness of nose, cheeks, etc., resulting from venous ectasia, and this is the laying waste of the pathologic, newly-formed ampullæ in the vessels. If quite superficial, they can be reached by applying a salve made of 10 parts beta naphthol, 40 parts sulphur, 25 parts green soap. This is applied once or several times a week for one-half to one hour and then wiped off dry. The skin becomes gradually accustomed to it, and it can then be applied oftener and longer. No inconveniences were observed in any of Lassar's numerous cases thus treated. Transient irritation from it at first is combated with talcum powder or a soothing salve. The amount of dilatation of the capillaries and veins can be best determined by the absorption of light under a powerful microscope, the tissues lighted from the side. He obliterates the lumen of the vessels by a special contrivance consisting of forty gold-plated platinum points, not too sharp, driven by an electromotor, piercing the skin with hundreds of fine pricks in a few seconds. Actual freezing should be treated the same as a burn, keeping the parts aseptic, dusting with a dry powder and dressing with bismuth, watching carefully for indications of gangrene. If this occurs and if it can not be kept dry under anilin blue, which has such remarkable antiputrefaction properties, the gangrened part must be treated like any infected wound. Phlegmons and pyemia are liable to follow the use of household remedies and easily-spoiling salves.

Chilblains, on the contrary, are notably benefited by salves, especially by a combination of the cerate of subacetate of lead, olive oil and carbolized vaselin. It is applied over night, smeared copiously on a cloth, and all signs of the chilblain soon disappear. When the hands become red and the redness recurs on exposure to cold, the circulation can be stimulated by gymnastic exercises. Both active and passive massage of the hand can be produced by holding the hand at the level of the shoulder with the wrist loose and snapping the fingers forward, at first slowly and then faster and faster.

**73. Flap-Treatment of Cicatricial Contractions.**—Wolff secured such good results in a case he describes and illustrates, that he recommends the method in similar cases of contraction. The young man's arm was bent almost like a Z in consequence of a severe burn years before. The wrist was cut across transversely on the side of the contraction, the incision avoiding the vessels and nerves, but carried down to the bone until every contracting fiber had been found with the finger and severed. The joint could then be mobilized at once. When the joint was straightened, the defect left by the gaping wound was nearly the width of the palm. This was closed by a pedunculated flap from the thorax. The elbow and thumb were treated later in the same way and almost complete function has been restored, without the excision of a scrap of tissue.

**74. Operative Treatment of Gastric Ulcer.**—Porges states that at Hohenegg's clinic operation in case of gastric ulcer is by Hacker's method when possible and by Wolfer's when it is impossible to pull the stomach forward or when the posterior wall is involved in the morbid process. In case the stomach is small, the entire walls infiltrated with carcinoma and adherent to the pancreas, Maydl's jejunostomy is to be preferred. In a case described a gastric ulcer in the lesser curvature had perforated, but as the wall was adherent to the liver at this point there was very little escape of stomach contents. The case was treated by detaching the liver and introducing a strip of gauze and a drain through the defect, after a Hacker gastroenterostomy had been done. Fluid food was given by the mouth at once; it flowed down into the intestines by its own gravity without seeking an outlet through the defect, which closed later spontaneously by granulation. The recovery was prompt and uneventful, evidently favored by the open treatment of the wound in the stomach and the direct communication into the small intestine.

**75. Pathogenesis of Choked Disc in Case of Brain Tumors.**—Elschnig states that choked disc is an interstitial inflammation, too early in its appearance and too pronounced to be merely the result of the tardy degeneration of the nerve. It must be due—in case of brain tumors—to the toxins generated in the tumor, which are swept to the optic nerve in the orbit by the cerebrospinal fluid. They penetrate into the lymph spaces and cause interstitial inflammation. The optic nerve is evidently predisposed to inflammation and is liable to react with the condition we call choked disc to any intracranial affection or neuritis as well as to a tumor in the brain. The increased pressure of the cerebrospinal fluid in case of tumors causes the serous accumulations in the papilla.

**79. Difference in Action Between Extracts of the Medulla and of the Cortex of the Suprarenal Capsules.**—Salvioli found that both of the extracts increased the blood pressure, but the extract of the medulla had a stronger and more durable action in this respect. The latter also affects the respiration, rendering it more frequent and superficial. The results of his tests establish the fact that the former stimulates and the latter paralyzes the inhibiting centers of the heart.

**80. Infectious Fevers in Mexico.**—Olvera calls attention to the atypical character of the infectious diseases that have prevailed in the City of Mexico since the extensive drainage operations have been under way. He states that cases of abnormal typhus have been numerous, also of pseudo-typhoid fever, true enteric fever, typhoid pneumonia, malignant measles, etc. He believes that only the mildness of the climate has preserved the city from serious ravages by these unusual, mixed diseases. The constitutions of the inhabitants are not tried by

excessive cold nor excessive heat and hence are more resistant than under the same conditions elsewhere.

**83. Filarial Lymphangiectasis.**—Maitland calls attention to the operation suggested by him in 1889 of removing the glands of the groin in cases of this condition, on the theory that they contain the parasites. His first operation was a success. Its practical value has been since fully established by the results obtained by other surgeons. The operation, however, is still condemned in some text-books, and therefore he brings up the subject. Three cases are reported. The objection raised to this operation for the removal of lymphatic varices and lymphadenocenes, that such operations are unscientific in principle and do not completely remove the varix and the obstruction to the lymph circulation, is answered by him that practice has proven it to be quite successful in relieving the patient from the periodic attacks of fever and pain. Three cases are reported illustrating this fact. The second objection, that such operations are liable to be followed by lymphorrhagia or lymphatic fistula, is not the experience of Madras surgeons. He has never seen such a result himself and never heard of it in the experience of others. The third objection, that such cases are prone to be attacked by septic inflammation or erysipelas, is also contradicted by experience. The point he especially wishes to emphasize is that the object of these operations is not to lessen the circulation of the lymph, but to relieve the patient from suffering, and here the result is satisfactory.

**85. Pani-Ghao.**—This condition, known locally in Assam as ground- or water-itch, effects especially the native laborers who go bare-foot. Bentley has investigated its etiology and finds that it is due to introduction of the larval ankylostoma duodenalis from the soil into which it is introduced through the habits of the natives in causing fecal infection of the soil. The wearing of shoes is known to be an almost certain preventive of the disease.

**88. Blackwater Fever.**—Moffat discusses the alleged importance of quinin as a cause in the production of blackwater fever. He remarks that he has himself suffered from the disease when he had had no quinin for two months. He has known cases of it where quinin could be absolutely excluded. His theory of the cause of the disease is that it is due to lack of care in the patient during the apyretic stage. An old malarial patient should go to bed directly he feels the first symptom of a malarial attack, even though the temperature is yet normal, and, if possible, should be kept in bed after an attack until it has been normal for at least twenty-four hours. In these cases he believes hemoglobinuria does not appear. Since quinin is the only really reliable cure for malaria, in crediting to it such a condition as blackwater fever we would be frightening the inexperienced and making them shy of employing it in sufficient doses, with the result of severer attacks of malaria accompanied by a heavier death rate.

**93. Rectal Injections in Dysentery.**—This form of treatment, Lillie remarks, does not appear to be very strongly supported, but he has tried it himself in several cases in South Africa and found it most useful. He gave very gentle injections of small quantities at a time, an ounce or so every few seconds, and two or three times a day. He generally used boric acid, 10 gr. to the ounce, and sometimes other antiseptics. It is an important point to give them often enough. The bulk of the enema is never less than 1½ pints, but it is very gently introduced and in this way no unpleasantness is complained of. He considers the saline treatment of dysentery to be on the same principle as this. The bowel is flushed out and toxic substances removed, and with these removed griping and tenesmus are relieved. Injections possess the advantage of introducing this fluid for flushing from without and not draining from the patient's already weakened system and of applying antiseptics to the local foci of disease.

**94. Asepsis in Surgery.**—Grimsdale's article is a plea for asepsis as opposed to antiseptics. He gives graphic curves, showing the difference in the temperature and pulse of some 80 cases under the two systems, 40 under each, and also gives credit to a surgeon of 100 years ago, Alanson, for suggesting

in principle this method. He quotes from his recommendations, which are surprisingly modern.

**96. Frontal ("Ophthalmic") Reflex.**—The object of Overend's article is to call attention to the more exact designation, "ophthalmic," which he offers, and to express the view that the symptom is a true reflex and obtainable from both the skin and the periosteum supplied by that nerve. He remarks that he first described it in 1896 under the name of "frontal reflex" and demonstrated it to medical friends as far back as 1889.

**101. Dental Caries.**—Goadby discusses the causes of dental caries, and concludes that it is largely due to carbohydrates, and the acid-forming bacilli. Proteids will tend to the reduction of caries; fermentative bacteria of the putrefactive class in that they tend to produce an alkaline reaction will also prevent the development of rapid caries. He attributes the great frequency of the condition among the European races to a defective condition of the enamel, and the fact that owing to the civilization of the race and the influence of sexual selection on the type of beauty as well as the large development of the frontal lobes of the cerebrum, the facial angle has been considerably altered, and with it the superior maxilla has become contracted with concomitant crowding of the dental arch. The teeth have remained for the most part of the same size. The result is that irregularity and crowding are common and a very fruitful cause of dental caries. The general physical condition of foodstuffs also differs; the hard, coarse and fibrous food is no longer used, and its cleansing effect on the tooth surface is replaced by the soft, smooth variety of food so commonly consumed. To prevent caries, he thinks much attention should be given to children from the appearance of the first temporary teeth. The use of the tooth brush should be taught early, and he recommends an alkaline antiseptic wash for the mouth and a dentifrice to be used. His article concludes with a table showing the approximate distribution of caries in the various races, from the Eskimo, 1.4 per cent., to the European, 87 to 90 per cent.

**102. Feeding in Typhoid.**—Brummitt's change from the orthodox mode of treating typhoid with liquid food alone is dated from a patient who ate up her poultice which had been ordered for an abscess, and since then he has used soft instead of liquid foods quite extensively. He reports a number of cases. The nurses observe that the patients do better, keep stronger, and he has seen cases where the desire for stronger food was expressed almost from the outset and as urgent as in the poultice case. He would assume in such that the digestive apparatus was in fair working order. He thinks when the digestive power of the stomach is good as it often is, a mutton chop, an egg, a banana, or a cup of milk would reach the cecum in very much the same form. He commences with light farinaceous foods and bread and milk, and goes on to mince meat, mashed potato with milk or gravy, custard, light boiled eggs with breadcrumbs or thin bread and butter; boiled white fish or fowl, brain, rice in various forms, etc., and some vegetables are often desirable, but he would remove the solid portions. Watchfulness as to the evacuations, however, must be continued, and if non-digested food is passed a change should be made at once. He does not advocate the indiscriminate use of strong food in enterica; adherence to milk diet would be better than that; but the judicious use of a larger dietary scale in many febrile cases and nearly all convalescents, would be good practice. A careful study of 98 cases leads him to conclude that the well-being of the patient generally is favored by the use of a more liberal diet.

**106. Typhoid.**—The difference of opinion as to the frequency of typhoid in the East Indian natives is noticed by Rogers, who says that it is decidedly frequent in those of Calcutta instead of their being immune. Nearly every case in which the temperature remains high for three weeks or more continuously in natives, is enteric, while mild or abortive cases of shorter duration are exceptional. It is not always easy to diagnose with certainty typhoid in these patients until very late in the disease by clinical means, but great assistance can be obtained by the skilled use of the Widal test.

## Queries and Minor Notes.

### CURE OF ALCOHOLIC AND MORPHIN HABITS.

UPPER SANDUSKY, OHIO, Jan. 28, 1902.

To the Editor:—Would you be so kind as to state in your next issue what the willow-bark cure for alcoholic and morphin habits is which is now being so prominently brought before the public? Also, what treatment, if any, is the best for the above-named habits in your opinion, and oblige.

W. W. S.

ANS.—As regards the "willow-bark cure" we have no reliable information; it is probably a bitter tonic. The question is referred to our readers for reply. With regard to the best treatment for the alcohol habit, we believe that a strong moral impulse is the most effectual and lasting one in present conditions, as well as the safest one, and that without it or absolute restraint, almost any other treatment will probably fail. As regards the morphin habit and its cure, we would refer to the abstracts of Jennings' paper in the London *Lancet*, which appeared in THE JOURNAL of Aug. 31, 1901; of McBride's paper in THE JOURNAL of Sept. 1, 1900, and the articles and discussion in THE JOURNAL of August 18, of that year.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume III. The Eye, Ear, Nose and Throat; Edited by Casey A. Wood, C.M., M.D., Albert H. Andrews, M.D., and T. Melville Hardie, A.M., M.D. December, 1901. Cloth. Pp. 346. Price, \$1.50. Chicago: Year-Book Publishers.

CHARTER, ORDINANCES AND BY-LAWS OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, as Amended June 14, 1899, with an Appendix Containing Articles of Agreement and Deeds of Trust, and the Rules Providing for the Creation and Government of Sections of the College, as Amended April 1, 1896. Paper. Pp. 124. Philadelphia. 1900.

DIGEST OF CRITICISMS ON THE UNITED STATES PHARMACOPEIA. Seventh Decennial Revision (1900) Published by the Committee of Revision of the Pharmacopeia of the United States of America (1900-1901). Part III, Comprising Abstracts of Papers up to May 15, 1901. Pasteboard. Pp. 181. Philadelphia. 1901.

CHEMICAL PATHOLOGY IN ITS RELATION TO PRACTICAL MEDICINE. By C. A. Herter, M.D., Professor of Pathological Chemistry in the University and Bellevue Medical College, New York. In one 12mo volume of 454 pages. Cloth, net, \$1.75. Philadelphia and New York: Lea Brothers & Co.

THIRTY-FOURTH ANNUAL REPORT OF THE BOARD OF WATER COMMISSIONERS OF THE CITY OF MIDDLETOWN, N. Y., for the Year Ending January 31, 1901. Paper. Pp. 70. Middletown, N. Y.: L. S. & J. D. Stivers, Printers. 1901.

PROCEEDINGS OF THE CONNECTICUT MEDICAL SOCIETY, 1901; 109th Annual Convention, Held at Hartford, May 22 and 23. Published by the Society. Cloth. Pp. 350. Bridgeport, Conn.: The Farmer Publishing Co.

MUNICIPAL ENGINEERING AND SANITATION. By M. N. Baker, Ph.B., C. E., Associate Editor of *Engineering News*. Cloth. Pp. 317. Price, \$1.25. New York: The Macmillan Co. 1902.

TRANSACTIONS OF THE RHODE ISLAND MEDICAL SOCIETY. Vol. VI.—Part II, 1900. Paper. Pp. 277. Providence: Snow & Farnham. 1901.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., January 23 to 29, 1902, inclusive:

I. P. Agostini, contract surgeon, leave of absence from the Department of Cuba is extended one month.

James B. Ferguson, contract surgeon, from Fort Yellowstone, Wyo., to his home, Olivia, Minn., for annulment of contract.

William C. Gorgas, major and surgeon, U. S. A., in addition to his present duties is assigned as disbursing officer of the Medical Department at Havana, Cuba.

Henry S. Kiersted, lieutenant, and asst.-surgeon, U. S. A., now at San Francisco, Cal., assigned, on the expiration of his present leave of absence, to duty at the General Hospital, Presidio of San Francisco, Cal.

John A. McAlister, contract dental surgeon, now at San Francisco, Cal., to report to the commanding general, Department of California, for transportation to Manila, P. I., for duty in the Division of the Philippines.

Edgar A. Mearns, major and surgeon, U. S. A., from Fort Adams, R. I., to Fort Yellowstone, Wyo.

Edward B. Moseley, major and surgeon, U. S. A., president of a board at Denver, Colo., to determine the fitness of officers of the Army for promotion.

George J. Newgarden, captain and asst.-surgeon, U. S. A., member of a board at the General Hospital, Presidio of San Francisco,

Cal., for the examination of candidates for admission into the Medical Department of the Army, vice Captain William H. Wilson, asst.-surgeon, U. S. A., relieved.

Ogden Rafferty, major and surgeon, U. S. A., member of a board at the general hospital, Presidio of San Francisco, Cal., for the examination of candidates for admission to the Medical Department of the Army, vice Major Robert Gibson, surgeon, U. S. A., relieved.

Henry H. Rutherford, lieutenant, asst.-surgeon, U. S. A., from the Division of the Philippines to duty at the General Hospital, Presidio of San Francisco, Cal.

Louis A. Thompson, contract surgeon, leave of absence on account of sickness extended two months.

Charles W. Thorp, contract surgeon, relieved from duty in the Division of the Philippines, and at the General Hospital, Presidio of San Francisco, Cal., to accompany the 4th Infantry to Fort Sam Houston, Tex., whence he will proceed to Fort Clark, Tex., for assignment to duty.

Philip G. Wales, captain and asst.-surgeon, U. S. A., member of a board at Denver, Col., to determine the fitness of officers of the Army for promotion.

William A. Wickline, contract surgeon, from Butte, Mont., to duty at Fort Lawton, Wash.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending Feb. 1, 1902:

Rear Admiral W. K. Van Reypen, detached from duty as chief of the Bureau of Medicine and Surgery, Navy Department, and ordered home and to wait orders.

Asst.-Surgeon C. M. Oman, commissioned asst.-surgeon from Dec. 18, 1901.

Asst.-Surgeon G. M. Mayers, detached from the Naval Hospital, Cavite, P. I., and ordered to the *Isla de Cuba*.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 1, 1902:

#### SMALLPOX—UNITED STATES.

Arkansas: Little Rock, Jan. 20, 17 cases, 1 death.  
California: Los Angeles, Jan. 11-18, 8 cases; San Francisco, Jan. 12-19, 4 cases.

District of Columbia: Washington, Jan. 11-18, 2 cases.  
Illinois: Jan. 18-25, Belleville, 1 case; Chicago, 8 cases; Danville, 1 case; Freeport, 3 cases; Galesburg, 2 cases.

Indiana: Evansville, Jan. 18-25, 4 cases.  
Iowa: Clinton, Jan. 18-25, 5 cases.

Kentucky: Lexington, Jan. 18-25, 3 cases.  
Maine: Portland, Jan. 18-25, 1 death.

Massachusetts: Boston, Jan. 18-25, 44 cases, 6 deaths; Cambridge, Jan. 18-25, 3 cases, 1 death; Lowell, Jan. 18-25, 1 case; New Bedford, Jan. 18-28, 6 cases; Somerville, Jan. 18-25, 1 case; Weymouth, Jan. 11-18, 1 case, 1 death; Woburn, Jan. 18-25, 1 case.

Michigan: Detroit, Jan. 18-25, 6 cases.  
Minnesota: Minneapolis, Dec. 28-Jan. 18, 57 cases.

Missouri: Hannibal, Jan. 11-18, 1 case.  
Nebraska: Omaha, Jan. 18-25, 54 cases.

New Hampshire: Nashua, Jan. 18-25, 3 cases.  
New Jersey: Camden, Jan. 18-25, 19 cases, 1 death; Jersey City, Jan. 18-26, 13 cases, 1 death; Newark, Jan. 18-25, 35 cases, 8 deaths.

New York: Jan. 18-25, Binghamton, 1 case; New York, Jan. 18-25, 54 cases, 11 deaths.

Ohio: Cincinnati, Jan. 17-24, 17 cases; Middletown, Jan. 18-25, 1 case; Toledo, Jan. 18-25, 1 case; Youngstown, Jan. 18-25, 4 cases, 4 deaths.

Pennsylvania: Altoona, Jan. 8-25, 1 case; Norristown, Jan. 18-25, 1 death; Philadelphia, Jan. 18-25, 90 cases, 19 deaths; Pittsburg, Jan. 18-25, 2 cases; Reading, Jan. 20-27, 1 case; Scranton, Jan. 15-22, 1 death.

Rhode Island: Providence, Jan. 18-25, 2 cases.  
Tennessee: Memphis, Jan. 18-25, 16 cases.

Vermont: Burlington, Jan. 18-25, 31 cases.  
Washington: Aberdeen, Jan. 18, prevalent; Coupeville, Jan. 16, 2 cases; Hoquiam, Jan. 18, prevalent; Tacoma, Jan. 12-19, 3 cases.

Wisconsin: Green Bay, Jan. 19-26, 13 cases; Fond du Lac, Jan. 18-25, 1 case; Milwaukee, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

Yosemite: Yosemite, Jan. 18-25, 3 cases.

### AN EXPERIMENTAL AND CLINICAL RE- SEARCH INTO COCAIN AND EUCAIN.\*

GEORGE CRILE, M.D.

CLEVELAND, OHIO.

#### EFFECT ON PERIPHERAL NERVE TRUNKS.

The injection of eucain or cocain into a nerve trunk so as to place all its structures in contact with the drug produces an effectual physiologic "block." By the word "block" is meant such condition of the nerve that neither afferent nor efferent impulses can pass, the conductivity being as completely interrupted as if the nerve were divided. While general anesthesia prevents the appreciation of pain and the production of voluntary motion, it does not prevent such other afferent impulses as those caused by mechanical, thermal or electrical stimulation of the nerve endings or trunks, which produce changes in the frequency and the amplitude of the respirations, in the frequency and force of the heart beats, and in vasomotor action. Either eucain or cocain injected into a nerve trunk as above described prevents the passing of such afferent impulses, thereby preventing effects upon the respiration, the heart or the vasomotor mechanism, i. e., shock. Under general anesthesia, if the paw of an animal is subjected to the flame of a Bunsen burner, after the lapse of a short time the leg is drawn up by the contraction of groups of muscles in a deliberate but rather forcible manner, removing the foot from the flame. General anesthesia, no matter how deep nor what anesthetic employed, does not prevent such action of the muscles. It seems, if the expression may be allowed, to be an "unconscious purposive" action. Either eucain or cocain injected into the path of these afferent impulses prevents this phenomenon. If it is intended to produce an immediate effect it is necessary to make a thorough injection. If a little time is allowed to elapse, the solution need not be directly injected into all the parts of the nerve trunk. Even if injected underneath the sheath, without penetrating the substance of the nerve trunk, a "physiologic" block may be produced. No unfavorable later effects were noted. In a number of cases in which the nerves were thus blocked, and the animals allowed to recover, there was but temporary functional impairment, and in no instance was there evidence of neuritis or of degeneration following. The effect of the eucain and cocain upon nerve structures is apparently the same as their well-known general effects upon the protoplasm; that is, they temporarily suspend its functional activity.

They form no chemical combination and cause no destruction either of its physiologic properties or of its substance. As to afferent impulses, it was found that the cortical discharges of the brain were blocked either when they originated as a voluntary action, or when they originated as an artificial convulsion produced by the administration of the essential oil of absinthe. Even powerful electrical currents applied to the nerve trunk, near the block, were found to be incapable of forcing their impulses through the "block." What has been said of the effect of cocain thus applied to the nerve trunks may be said of like injections into the spinal cord. The effect upon the optic nerve is that of at least partially blocking the impulses of the light waves and were the injections given directly into this nerve the "block" would probably be complete. Either eucain or cocain when applied upon the medulla or fourth ventricle within a few seconds suspends the action of the respiratory center. This suspension is characterized by a gradually increasing slowness of respiration, together with gradually decreasing amplitude, so that within thirty seconds respirations cease. The blood pressure in nearly every instance suffers a profound depression, the nature of which is a gradual decline such as is observed on making a cross-section of the cervical spinal cord; that is to say, the vasomotor center or paths are anesthetized. Another effect of the application of eucain or cocain upon the medulla or the floor of the fourth ventricle is immediate complete general anesthesia and immediate total loss of all voluntary action. The corneal reflexes are at once abolished and the pupils are dilated. When the paws of the dog are exposed to the flame of a Bunsen burner the legs are not drawn up, the blood pressure is not altered, and the heart's action is not affected. It is needless to say that there are no respiratory changes. In other words, application of these anesthetics upon the medulla or the floor of the fourth ventricle suspends temporarily all the manifest functions of that organ excepting the heart's action, and that is modified. General anesthesia may be indefinitely prolonged by repeated applications. Upon the vagi the effect of an injection of these drugs is to suspend their inhibitory action. The action of cocain is probably a little more prompt than that of eucain; the latter, however, seemed to be quite as effective as the former. Cocain and eucain block the impulses set up by electrical stimulation in nerve trunks even after death; that is, if after the death of an animal a nerve trunk is stimulated, within a certain time the muscles supplied will be thrown into contraction; but if cocain or eucain is injected into the nerve trunk and a stimulus applied above it, no contraction will occur.

\* The experimental research consisting of 89 experiments on animals, mostly dogs, will be published in detail elsewhere. This paper is a summary.

The physiologic action of cocain and eucain, both local and general, are so nearly alike that one description may serve for both. The first effect, observed after

Fig. 1.—*a*, Respiration; *b*, blood pressure; *c*, signal; *d*, seconds. Injection in lumbar region with considerable force, showing how quickly both the respiratory and the vasomotor centers may be paralyzed. The secondary rise in the blood pressure was due to the first disturbance of the convulsive center in the medulla.

the intravenous injection, is a temporary increase in the blood pressure. This increase appears almost immediately, and continues for a brief period of from five to twenty seconds, when the blood pressure returns to or near its former level. The heart strokes forming the curve are usually a little shorter, and the rapidity of the heart's action somewhat increased. No definite vasomotor change was indicated by the peripheral venous or peripheral arterial manometers. A water manometer recording the splanchnic blood pressure indicated a rise out of proportion to the rise in the general blood pressure. In rare instances there was a fall in the blood pressure, but compensation was immediately inaugurated and the lost pressure was quickly regained. In overwhelming doses with lethal effect the general blood pressure, in fact, all the pressures, rapidly sink to the abscissa line. It was noted that when the animal was under the systemic effect of these drugs the blood pressure curve was, as a rule, not so regular as under normal conditions. It was also noted that in a number of experiments the length of the stroke of the writing style, expressing the heart's action, was shortened under the systemic effects of these drugs. This ir-

regularity of the blood pressure curve was similar to the irregular curve when the animal was under physiologic dosage of atropin or when both vagi had previously been severed. It was also found that when animals were under the effect of these drugs, stimulation, by applying the electrodes upon the vagi, did not produce normal characteristic effect; that is to say, that while in normal conditions the application of a Du Bois Reymond electrode upon the vagi causes slowing or arrest of the heart; in animals under the systemic influence of cocain or eucain the application of such stimulation to the vagi in most instances produced little or no effect. In a number of experiments it was observed that if after having secured a control tracing of the inhibitory effect of intralaryngeal manipulation the animal was subjected to a physiologic dosage of cocain or eucain, a like manipulation of the larynx usually produced no inhibition. In the experiments in which inhibition was noted it was in most instances less than normal. The same may be said of other experiments upon the superior laryngeal nerve. The physiologic effect of cocain and eucain in this respect is quite analogous to that of atropin, though the effect is not so marked. The increase in the blood pressure after the administration of cocain is in a measure similar to that which follows section of both vagi. Taking into consideration all of the evidence, it would seem that cocain and eucain partially or wholly suspend the inhibitory function of the vagi, whether produced by direct or indirect stimulation. While not prepared to make a positive statement on the subject, it appears that the increased rapidity of the heart's action under the influence of these drugs was due to the removal of the vagal influence and not to

stimulation of the accelerators. The splanchnic area, especially the veins, when the abdominal viscera were subjected to exposure or irritation, or both, was dilated.

the intestines became red, extremely congested, and often livid. When the animal had been given a physiologic dose of cocain or eucain and exposed to like experiment the splanchnic vessels did not dilate, except-

Fig. 3.—*a*, Respiration; *b*, blood pressure. As a control the hind foot was burned, causing a rise. Then cocain solution was injected into lumbar region, after which burning of the foot caused no effect upon either the blood pressure or the respiration.

ing those at the bases of the intestines. The arteries became decidedly smaller and the intestines a peculiar palish red. In a large series of control experiments it was found that with but rare exceptions such irritation

or exposure of the splanchnic area caused a fall in the general blood pressure proportional to the exposure or irritation and the condition of the animal. In some instances the fall was extremely rapid and the animal soon died, but in a series of experiments in which cocain was systematically administered there was but a slight, if any, fall in the general blood pressure. There was a striking difference between the results in the control experiments and the "cocain" ones. In order to make the comparisons more reliable double experiments were performed. Two animals of as nearly the same size and under as nearly the same conditions as possible were placed side by side on similar dog boards, and precisely the same experiments were performed simultaneously upon each. In every instance the benefit of any doubt was allowed the control dog. The writing style recording the blood pressure and the respiratory action of each was placed in a vertical line, so that direct comparisons could be accurately made. The result of these double experiments may be summarized as follows: In the control dogs exposure and manipulation of the intestines produced a fall in the blood pressure; in the cocain and eucain dogs, as a rule, no fall occurred. The cocain and eucain dogs endured more mechanical injury than the control dog. The latter in every experiment died first. In burning the hind feet in the animals the blood pressure in the control rose higher and more promptly than in the cocain or eucain dogs. In crushing the testicle the blood pressure fell more promptly and a greater distance than in the cocain or eucain dogs. The same may be said of the manipulation of the larynx, stimulation of the vagi, operations in the pharynx, in short, of every portion of the body. The comparison between the appearance of the abdominal viscera in the control dog and that in the cocain or eucain dog is that in the latter the intestines were of a peculiar shade of pale red, and the vessels were, if any change was noted, of less caliber than before the experiment; while in the control dog all the vessels were engorged, the viscera exceedingly red, and in many instances livid. It was at once apparent that the difference in the blood in the splanchnic area of these two animals was very great. Even the inferior vena cava was smaller in the cocain animals. The effect upon the circulatory apparatus: first, an immediate rise takes place in the blood pressure lasting a few minutes; this is followed by a compensatory fall; later, a gradual rise occurs. The inhibitory influence of the vagus is partially or wholly suspended. The vasomotor reflexes are considerably lessened. The circulatory apparatus is less responsive to stimulation. The latent period of vasomotor reflex action is markedly increased. The vessels of the splanchnic area are contracted.

There is but little doubt that there is an increased tendency to clotting. Upon the respirations a small dose seemed to act as a stimulant. A medium dose seemed to lessen the length of the respiratory stroke, while a large dose caused respiration to gradually diminish. It was frequently observed that if a series of injections of these drugs were administered at given intervals a very marked tolerance was acquired, so that finally but little effect could be produced. It was also observed that animals under the influence of these drugs were more difficult to maintain in the condition of even surgical anesthesia. More general anesthesia seemed to be required, and the animals had a tendency to come unexpectedly out from its influence.

## SPINAL CORD ANESTHESIA.

*Injection into the Spinal Cord.*—In 1897, after performing the experiments upon nerve trunks showing that cocain was capable of producing physiologic section, that is to say, the afferent or efferent impulses could not pass the point cocainized, and after having performed amputations on the human subject without pain and without shock by this method, similar procedures upon the spinal cord were suggested. The experiments along this line consisted in injecting the solution directly into the substance of the cord. This produced immediate anesthesia at all the points with which the cocain came in contact. Although the anesthesia was immediate and complete, and for operative purposes was entirely satisfactory, it was obvious that this procedure necessitated a physical damage to the cord.

Recovery experiments were made as follows: The cord was anesthetized by injecting cocain directly into its substance by means of a fine needle. The complete-

of cocain with the cord. The depth of the fall was proportional to the completeness and the anatomical parts involved. The curve in the descent of the blood pressure was gradual and even, after which a regular line was maintained for some distance, which indicated the loss of vasomotor control. The effect upon the blood pressure when the medulla or the fourth ventricle was cocainized was the greatest, the pressure falling almost to the abscissa line. When the entire cord had been subjected to the influence of cocain and the pressure had fallen as above described, if any part of the body below the level cocainized was subjected to burning, crushing, or any other mechanical, thermal or electrical stimulation, no rise in the blood pressure occurred. There was usually but a trifling amount, if any, of compensation after the fall of the blood pressure until the cocain effects passed off.

Effects on Respiration: The immediate effects on the respiration, after a subarachnoid injection of a compara-

Fig. 4.—a, Blood pressure; b, signal; c, seconds. This experiment shows that after an injection in the thoracic region manipulation of the abdominal viscera does not affect the blood pressure.

ness of the anesthesia was proved, the animal allowed to recover, and after a lapse of varying periods of time was killed. The cord was subjected to microscopic examination. While in some of the cases it was impossible to detect any microscopic damage to the cord, there was found some round-celled infiltration and disturbance of the histologic arrangement. It was at that time concluded that this was not a justifiable procedure in any but most exceptional cases. Later experiments were made by injecting cocain into the subarachnoid space. In dogs this space is so small that it is necessary to expose the cord in order to make an injection without traversing the cord. The injection of a 1 per cent. solution of cocain into this space produced almost immediate anesthesia.

*Subarachnoid Injection.*—Effect on the Circulation: The effect of injecting a solution of cocain into the subarachnoid space in the lumbar region was an immediate fall in the blood pressure, the beginning of the fall being almost coincident with the contact of the solution

Fig. 5.—a, Respiration; b, blood pressure; c, signal. This experiment shows how quickly an injection in the lumbar region may kill, and that after the effect is obtained burning of the feet does not produce any change in the blood pressure.

tively small amount of cocain in any part of the spinal cord, not involving the medulla, is acceleration. The application of a 1 per cent. solution of cocain upon the medulla or the floor of the fourth ventricle produced within a period of time ranging from a few seconds to a few minutes, complete respiratory paralysis. There is first loss of the intercostal and extraordinary muscles, then the abdominal muscles and lastly the diaphragm. The action of the diaphragm becomes shallower at each contraction until it is entirely paralyzed.

The membranes of the cord are so nearly inelastic that for the present purpose they may be regarded as being so, while the cord itself is so nearly incompressible that it may be considered so. The subarachnoid space is always filled with its own fluid. If additional fluid is added, it must cause a displacement similar to that of fluid in a capillary glass tube. The rapid and uncontrollable ascent of the anesthesia of the cord was most striking. In order to better study this a series

of injections was made with cocain solution colored with methylene blue. It was found that an ordinary injection in the lumbar region of one-half dram of this solution stained the entire cord and the under surface of the brain within thirty seconds. All the various localized functions of the cord and medulla were with rapidity anesthetized. The respiratory center in the medulla, for example, could be anesthetized by a lumbar subarachnoid injection within a few seconds, so rapidly did the fluid pass up the cord. Marked fall in the blood pressure and cessation of the respiration occurred within a few seconds, after a rather forcible injection in the lumbar subarachnoid space. The fluid ascended about as readily in the vertical posture as in an horizontal. There can be but little doubt that the effect is due to the local contact of the nerve structure and not to absorption. This view is in full accord with the action of cocain on other nerve tissue. A solution injected with

data have been corroborated. This was most strikingly exhibited in a case described by Fowler in which the anesthesia during three minutes extended up to the level of the clavicle, at which time the patient became cyanotic and artificial respiration was necessary. Other observers have noted the marked effect on respiration, the lowered blood pressure, and the rapid pulse, the latter indicating that the cocain solution was affecting the centers of the medulla. In 692 reported cases there were six deaths that were attributable to the anesthesia, a mortality rate at least fifty times greater than that of chloroform.

#### CLINICAL APPLICATION OF THE EXPERIMENTAL EVIDENCE.

*Operations on the Extremities.*—Leg: The "blocking" method was employed independently by Dr.

Fig. 6.—Showing the most accessible portion of the anterior crural nerve.

considerable force into the lumbar subarachnoid space was attended immediately by convulsions. The convulsions were due to the stimulation of the convulsive center in the medulla. The dosage used in these experiments was purposely made large to determine the control, or rather the want of control, the operator could have upon the extent of the anesthesia. In control experiments in which normal saline solution was injected into the spinal cord an immediate fall in the blood pressure occurred, but compensation quickly followed. The respirations were but slightly affected. There was the most striking difference between the overwhelming paralysis in the one case and the want of it in the other. The experiments showed that the operator has but little control over the extent of the anesthesia produced under the subarachnoid injection. While direct injection into the cord gave a complete control of the extent, it produced a distinct mechanical lesion. In the clinical reports of the subarachnoid anesthesia these experimental

Fig. 7.—Showing the most accessible portion of the sciatic nerve.

Rudolph Matas of New Orleans, of which his brilliant monograph on anesthesia gives a full account. Applying the so-called physiologic "blocking" properties of cocain or eucain to surgical practice, we have been enabled to perform certain operations upon the extremities without causing pain and shock by injecting a 1 per cent. solution of cocain into the supplying nerve trunks. The external cutaneous nerve is so superficial that it is readily accessible. The anterior crural is readily exposed in its relations with the artery, and the sciatic at the margin of the gluteal fold along the inner border of the biceps muscle. In operations performed upon the area supplied by the "blocked" nerve trunks the afferent impulses can not reach the central nervous system. There is, therefore, neither pain nor shock. This method is of the greatest possible importance in operations in which general anesthesia is contraindicated. The operation under these circumstances can cause no more shock than if the member had no connec-

tion with the body, as the "block" for such purposes is equal to a physiologic amputation.

In this manner I have five times performed amputation of the leg below the knee, and in all but one the patient was not aware that the operation was performed until told of it afterwards. It is necessary to control the patient well. After preliminary preparations have been made, the patient's attention should be diverted. I have usually said that an examination and a dressing would be made requiring considerable time, and that the operation would be performed next day. In the meantime the eyes were covered. In the one case the patient became aware of the progress of the operation by hearing the noise of the saw while dividing the bone. The "block" continues from twenty-five to thirty minutes. The clinical observations are in entire accord with the experimental evidence.

Operations in the Area of the Distribution of the Ulnar Nerve: The superficial position of this nerve at

CASE 2.—A small boy discharged a pistol, which took effect in the ulnar side of the hand, tearing away the soft parts and a portion of the fifth metacarpal bone. By "blocking" the ulnar nerve at the elbow the wound was examined, and the fragments of the bone removed without pain. In this case there was no complaint of the burning sensation described in the preceding. The wound healed readily.

CASE 3.—In a tuberculous patient a local focus appeared in the metacarpal-phalangeal joint. In performing an operation for the removal of this focus, the ulnar nerve was "blocked." At first an attempt was made to secure anesthesia by injecting the solution around the nerve, but after waiting five minutes it was found that anesthesia was only partial and that it was necessary to inject the nerve itself. In performing the operation it is best to fix the nerve well against the bone and insert the needle gradually as anesthesia occurs in advance of the needle. After such an injection the anesthesia was complete and the operation was performed painlessly. The patient complained of some burning the first night, but the second day it decreased and was not again experienced.

In two other cases this nerve was in a similar manner

Fig. 8.—Point of election in making the incision for exposure of the subclavian artery and the brachial plexus.

the elbow joint enables the surgeon to apply a cocaine or a eucain "block" almost painlessly by inserting a hypodermic needle, first into its close vicinity, then into the trunk itself, injecting the solution on its way. After the lapse of ten minutes the entire area supplied will be rendered anesthetized, and if the patient's attention is diverted operative procedures, such as amputations and resections, may be performed painlessly and without the patient's knowledge.

CASE 1.—A railway employe, whose hand and little finger were severely crushed within the area of the distribution of the ulnar nerve, required amputation and revision. Bending the elbow, a wheal was produced by injecting a 1/12 per cent. solution of beta-eucain, thereby creating a painless path to the nerve trunk, which was then anesthetized. In a few seconds there was complete anesthesia, and the finger and the corresponding metacarpal bones were removed while the patient was an interested spectator. The night following this operation the patient complained of a burning sensation over the distribution of this nerve. There was some local tenderness at the point of injection, but this disappeared after several days.

Fig. 9.—Showing the point of election for exposing the subclavian artery and the brachial plexus.

"blocked." In each the anesthesia was complete in five to ten minutes and no after-effects were noted. In no case was there any interference with the function of this nerve in consequence of the injection. Neither did the points at which the injection was made remain tender. No neuritis followed.

*Amputations at the Shoulder Joint.*—Amputations at the shoulder joint are usually indicated on account of a serious accident or disease, and in consequence such operations are frequently performed under unfavorable circumstances. There has been considerable mortality following this operation, even under the more favored conditions. In operations for malignant disease in the aged, and operations in the presence of profound depression or shock, general anesthesia adds seriously to the danger. There are many instances of contraindication to the use of general anesthesia. A method by which this operation may be performed without general anesthesia, without shock and without hemorrhage, was devised in accordance with the experimental evidence

set forth in the preceding pages, and put into practice in June, 1898.

**Technique:** The technique is based upon the fact that nerve trunks may be safely and effectually subjected to a physiologic "block" by injecting cocain or eucain in a comparatively weak solution, and that arteries may be, with entire safety, temporarily closed without injuring their walls. Fortunately, in the application of these principles, in amputation of the shoulder joint the subclavian artery is in close surgical relation with the brachial plexus so that the same incision may be utilized for exposing the nerve and the blood supply.

**CASE 1.**—Female, aged 74, was suffering from sarcoma of the arm, situated in the lower third and extending well down to the elbow. There was a metastatic growth in the axilla. She was suffering great pain and the tumor was growing

extending the dissection a trifle farther downward and inward the arching subclavian artery was brought into the field. In making this dissection it is important to keep the field of the operation entirely free from blood, so that the translucency of the tissue will permit the ready recognition of the anatomic structures in their minutest detail. It will then be possible to detect small nerve twigs before they are encountered and enable the operator to subject them to local anesthesia in advance. In this way the area supplied by these branches may be anesthetized. The small vessels may be caught with narrow-bladed forceps, between which the incision may be carried. The smaller nerve twigs are usually found running along the blood vessels or in the connective tissue planes. It was observed in this dissection that in the deeper structures the sensory nerve supply is not so abundant as in the more superficial. After exposing the trunks of the brachial plexus, there being but a slight amount of pain in the dissection, they

Fig. 10.—Showing sarcoma of the head of the humerus, involving the scapula.

rapidly. Owing to her extreme age, an amputation at the shoulder joint by the methods hitherto in vogue, giving a general anesthesia without "blocking" the nerve trunks to protect her against the afferent impulses caused by the mechanical irritation of the amputation and thereby producing shock, would have been a risk too great to assume. It was decided to perform the operation by employing the technique above described. An incision was made along the outer border of the sternomastoid muscle under 0.1 per cent. infiltration cocain anesthesia. The incision was carried through the superficial and the deep fascia, exposing in the first part of the incision the external jugular vein. The lower part of the incision was carried well down on the clavicle. The omohyoid muscle was retracted downward, the anterior angle of the trapezius backward and the posterior margin of the scalenus anticus forward, thereby exposing the trunks of the brachial plexus, and by

Fig. 11.—Patient upon whom excision of the left half of the shoulder girdle was made.

were subjected to a physiologic blocking by injecting first on their outer covering, then into their substance, a 0.5 per cent. solution of cocain, just sufficient to cause a localized swelling. It required but a small amount of solution. After injecting each trunk there was a total loss of sensation and of motion in all the parts supplied by the brachial plexus. The subclavian artery was then closed by means of a special clamp, over the blades of which rubber tubing was drawn. The blades were then approximated by adjusting the screw sufficiently to close the lumen of the vessel. The patient was then told that the operation would not be performed at that time, but would be deferred until the next day. A towel was thrown over her eyes, and under the pretext of making a careful examination of her arm the amputation was made without her knowledge. The flap on the outer and posterior aspects over the deltoid was made rather low, because of the sub-

cutaneous distribution of the branches of nerves from the cervical plexus, which, of course, had not been included in the physiologic block.

She experienced no pain except a slight one as the incision was carried around the posterior surface of the upper portion of the arm supplied by the supra-acromial nerve. The pain was, however, comparatively slight and was felt only during the incision of the skin. During the disarticulation the patient was not aware that she was being touched. After the operation had been completed it was found that there was absolutely no shock and that the operation had made no appreciable impression on her. The vessels were all picked up and tied before releasing the clamp from the subclavian. The total amount of cocain used in the operation was about  $\frac{1}{8}$  grain. A portion of this amount was recovered by sponging away the free solution in the wound. When the patient was returned to her bed she was not aware that her arm had been removed. She soon missed it, and manifesting some excitement, was informed by the nurse. She experienced some pain for a few hours after the operation and vomited several times the first night. She made a good recovery from the operation and there was nothing in the after-progress of the case different from operations performed in the usual way.

CASE 2.—Amputation of the arm at the middle was performed by the same technique as the preceding without producing any pain and without the slightest shock. Patient made a good recovery. The operation was performed on account of moist gangrene of the forearm in a patient having advanced pulmonary tuberculosis.

*Amputation of Half the Shoulder Girdle.*—This operation has been performed a number of times by various methods. The purpose of discussing it is to point out a technique by means of which hemorrhage and shock may be wholly avoided. Under general anesthesia an incision is made over the clavicle and the inner half of this bone is resected, after which the subclavian vein and the trunks of the brachial plexus are exposed. The trunks are then subjected to a physiologic block of cocain and eucain in comparatively weak solution, say 0.5 per cent. The brachial plexus is next severed and the artery and vein closed by ligature. The incision for the further technique in removing the scapula will vary with the object for which the operation is done. The amount of shock will be limited to what will be produced by making the incision through the structures supplied by the nerves from the cervical plexus, which is almost nil.

*Observations on the Pharynx.*—Clinical experience, as well as physiologic experiments, have demonstrated that when the pharynx is subjected to a considerable manipulation, especially that portion nearest the glottis, reflex inhibition both of the respiration and of the heart may occur. The respiratory inhibition is the more frequently produced. In the cases in which manipulation required considerable force the heart may be inhibited, causing collapse. I have observed this reflex inhibition of both the heart and the respiration in removing a tumor of considerable size from the nasopharynx. In operations for removing adenoid growths from the nasopharynx these phenomena have also been observed. In extracting large foreign bodies collapse may be produced. Not infrequently, in performing difficult operations in this portion of the pharynx, reflex inhibition confuses the operator. The respiratory inhibition is likely to give the impression that the patient is suffering from a mechanical obstruction. The inclination might be to clear out the upper respiratory passage, but this additional

irritation would increase the symptoms. In the experiments it was found that reflex inhibition in this area may be prevented by the local application of a 2 per cent. solution of cocain. The solution may be as weak as an 1 per cent., or even a 0.5 per cent., and be effectual. A hypodermic injection of atropin prevents reflex inhibition of the heart. In cases necessitating the removal of adenoid growths and tumors of the pharynx the efficiency of these drugs was proved. It is advisable, before beginning the technique of an operation involving this area, to make a local application of a solution of eucain or cocain, and a hypodermic injection of atropin, to prevent reflex inhibition. If during an operation inhibition does occur, the distinction between inhibition and obstruction must be borne in mind, for if the case is one of obstruction there will be increased respiratory efforts, but if it is a reflex inhibition respirations instantly cease. In obstruction the pulse continues unaltered for some time before it becomes markedly slower. In reflex inhibition the pulse is instantly and markedly slowed or arrested.

*Laryngotomy.*—Not infrequently in this operation at the moment the larynx is opened the patient goes into a state of collapse from which he may not recover. This operation is more frequently performed on children, oftentimes in great haste, under the stress of circumstances. If the operation is performed through the cricoid, collapse at the moment of entering does not occur. If made higher, it is very likely to occur, the reason being that in the higher operations the inhibition area of the larynx is mechanically stimulated. This causes a reflex inhibition, as in operations upon the pharynx. The superior laryngeal nerves are endowed with very strong inhibitory functions which are more active in the upper part of the larynx. The clinical observations are in entire accord with the experimental evidence.

CASE 1.—Dr. M. called in a colleague to aid in performing a laryngotomy upon a child who had a grain of corn in the larynx. The operation was successful until the larynx was opened, when suddenly collapse occurred, resuscitation seeming impossible. During the first stages of the collapse the corn was removed. Artificial respiration was maintained for a time, though life seemed extinct, when suddenly respirations began and there was an uneventful recovery.

CASE 2.—I was called to see a child 3 years old having a large bean lodged in the larynx. The history of the case was that while playing the bean, in a fit of laughter, was inspired into the larynx. Paroxysms of coughing followed, occurring at intervals. Each time the child stopped breathing, it became cyanotic and apparently dead. After a brief interval respirations returned, another paroxysm soon followed with a repetition of the collapse. From these symptoms alone the location of the bean was diagnosed as being in the upper part of the larynx. An operation under local anesthesia was performed. The incision was made through the cricoid cartilage, below the so-called inhibition area, and the laryngeal mucosa was treated with a 2 per cent. solution of cocain, after which the larynx could be readily explored, the bean located and removed without inducing reflex inhibition.

Cases might be multiplied, but the foregoing are typical. The difference between reflex inhibition and obstruction is very marked. Reflex inhibition can not be produced by a foreign body at any point below the so-called inhibition area of the larynx. The importance of the use of local anesthesia, to prevent reflex inhibition in laryngeal operations, can not be overstated.

In all the operations upon the larynx, especially in laryngectomy and intralaryngeal procedures, the use of cocain and eucain is of the greatest importance. In laryngectomy especial attention has been called to the

collapse that not infrequently appears while removing the larynx from its attachments.

Bardenhauer encountered this three times in one case while inflating the Trendelenburg apparatus. In intubation sudden death frequently occurs, the collapse being due to reflex inhibition of either the respiration or the heart, or both. Cocain or eucain applied to the mucous membrane wholly prevents such reflex inhibition. If such local application can not be applied, all the necessary arrangements for the maintenance of artificial respiration may be made in advance. A hypodermic injection of atropin will prevent the cardiac inhibition, so that, without the use of local anesthesia, atropin, with artificial respiration, may be depended upon to carry the patient over the inhibition crisis. In 156 intubations, I have encountered reflex inhibition six times, twice fatal, and they occurred before the nature of the inhibition was comprehended. Since making use of the experimental data, no case has been lost from reflex inhibition or "laryngeal collapse."

Death can not occur as a result of reflex inhibition if a preliminary hypodermic of a physiologic dose of atropin is given. The use of cocain is not practical in intubations for diphtheritic stenosis.

#### CLINICAL SUMMARY.

In the clinical use of cocain and eucain particular attention is called to a most important feature, viz., that shock is almost wholly avoided, because all afferent impulses are blocked. It is now known that afferent impulses set up by injury or operation are the causes of shock. These impulses are but slightly modified by general anesthesia. The afferent impulse, constituting pain, is abolished by general anesthesia, but those affecting the vasomotor, the respiratory, and the cardiac mechanisms are not controlled; but cocain or eucain absolutely blocks their passage, making a physiologic amputation of the part. These anesthetics wholly prevent reflex inhibition, the principal causes of collapse in certain operations and injuries, e. g., operations on the larynx and pharynx. Given hypodermically, the experimental evidence shows that they diminish shock in operations on the splanchnic area and absolutely alter this area in the processes of operation or exposure, as abundantly proved by the series of double experiments.

I have had but two opportunities of testing this clinically, both in operations for gunshot wounds of the intestines, and in each the experimental evidence seemed to be corroborated. Comparative results require such a large number of observations that I prefer for the present to offer no more than the clinical suggestion.

### CANCER OF THE PENIS.\*

HENRY H. MORTON, M.D.

Clinical Professor of Genito-Urinary Diseases in the Long Island College Hospital; Genito-Urinary Surgeon to Kings County and Long Island College Hospitals and the Polhemus Memorial Clinic.

NEW YORK CITY.

Malignant disease of the penis occurs almost invariably as epithelial carcinoma and begins with about equal frequency on the inner surface of the prepuce or upon the glans.

According to Jacobson, its mode of commencement is varied. It appears most frequently as: 1. A wart or warty excrescence. 2. Sometimes, however, it makes its appearance as a small nodule or knot of induration under the surface of the mucous membrane. 3. Again, epithelioma is observed occurring under the form of a

superficial excoriation or raw patch, resembling the erosions found in balano-posthitis. 4. It may develop as an ulcer resulting from the transformation of a chancroid or the breaking down of an old cicatrix, or sometimes from a crack or tear on the margin of a tight foreskin.

In cases of extreme rarity epithelioma of the penis develops from the extension of the malignant process outwards from the urethra or upwards from the scrotum.

*Etiology.*—Under the head of predisposing causes, age plays an important role, and epithelioma of the penis is very rarely found except between the fiftieth and seventieth years.

The next most important predisposing cause is phimosis. Demarquay found that out of 59 cases of epithelioma of the penis 42 had long and phimotic foreskins, and many authors have called attention to the fact that the circumcised Jews are almost entirely free from this disease.

Fig. 1.—Incision dividing scrotum into two halves and exposing corpus spongiosum, urethra, corpora cavernosa and triangular ligament.

Even though the glans be covered with a long foreskin, if the individual attends to the daily cleansing of the balano-preputial sac, there is no opportunity for irritating secretions to be retained; but we notice that cancer of the penis almost always occurs in men in the lower walks of life, of neglectful and uncleanly personal habits.

Any condition which gives rise to a balano-posthitis, such as the retention of decomposed smegma and urine under a phimotic foreskin, particularly if aggravated by a gouty diathesis in the patient, excites a persistent and long-continued irritation. In an elderly person in course of time the simple inflammatory process undergoes a transition into carcinoma of a polymorphous type, composed of large pavement cells and small epithelial cells.

*Course.*—No matter in what form the disease had its origin, its course is one of extension at the edges, accom-

\* Read before the New York State Medical Association.

panied by ulceration and breaking down in the older parts, and in most cases this is attended by the formation of large vegetations or fungosities, resembling a cauliflower in shape. A thin fluid, of a most disgusting odor, which dries into scabs, is continually secreted.

As the cancerous process extends only by continuity, its advance through the corpora cavernosa is not rapid, but the lymphatics readily take up the infectious material, carry it to the glands in the groin, and these are usually involved quite early in the disease. The inguinal lymphatic glands are often the seat of a mixed infection if pyogenic bacteria have been conveyed to them through the lymphatics and cause them to become inflamed and suppurate.

**Diagnosis.**—Every warty or papillomatous growth or persistent erosion occurring on the glans penis or inner surface of the prepuce, in an elderly person, should always be regarded with grave suspicion.

Fig. 2.—Corpus spongiosum containing urethra dissected away from corpora cavernosa, cut through and hanging down at lower angle of the wound.

It is often difficult to differentiate simple papillomata or a chronic balanoposthitis from carcinoma, but the sore, together with a base which is hard, infiltrated and immovable, and an edge which is hard and infiltrated, would point strongly in the direction of epithelial carcinoma. The diagnosis could be definitely determined by cutting a small piece from the growth and subjecting it to microscopic examination. A gumma of the penis occurring in tertiary syphilis might be easily mistaken for epithelioma, but a few weeks' treatment with mercury and iodids would cause the gumma to disappear.

**Prognosis.**—The prognosis of epithelioma of the penis is of course fatal without operation, and death occurs in from one to two years. If the disease is seen early and the growth removed by amputation of the penis and extirpation of the groin glands the prognosis is good, but many cases come into the hands of the surgeon too late for a complete removal of all the foci of infection.

Winiwarter reports twelve amputations, of which five remained permanently well, one died of the operation and six had recurrences, three of which were in the stump and three in the glands.

**Treatment.**—As already indicated, complete removal of all deposits at the earliest possible moment offers the patient the only opportunity of saving his life, and the application of caustics only excites greater activity in the growth and is a waste of valuable time.

Two forms of operation are in use, and a selection depends upon the extent to which the inguinal glands and corpora cavernosa are involved.

**Operation.**—In amputation of the free portion of the penis, a 20 French sound is introduced through the meatus into the bladder to indicate the position of the urethra. A harelip pin is thrust through both corpora cavernosa at the root of the penis to hold in place a rubber band, which is made to encircle the penis and act

Fig. 3.—Charred stumps of corpora cavernosa after separation from pubes by burning through them with Paquelin cautery.

as a tourniquet. The skin of the penis is then cut through with a circular sweep of the knife and turned back an inch. The corpora cavernosa are then divided, down to the corpus spongiosum, which, with the urethra, is left to project like a spout for an inch, before being cut through. The tourniquet is then unloosened and at least four arteries will require ligation. The skin flaps are then sutured together and the urethra stitched to the margins of the skin flaps. A soft rubber catheter is tied in the bladder to prevent the urine from infecting the fresh wound.

Amputation of the entire penis is a much more serious operation than the former, but is demanded in the case of extensive infiltration of the corpora cavernosa with cancerous deposit.

The patient is placed in the lithotomy position and a sound is introduced through the urethra into the bladder. An incision is made along the raphe of the scro-

tum, splitting it into two halves. The dissection is carried down so that the corpus spongiosum is seen perforating the triangular ligament with the corpora cavernosa lying on either side and attached to the rami of the pubes (Fig. 1).

The corpus spongiosum containing the urethra is then dissected away from the corpora cavernosa for three inches, cut through and allowed to hang down out of the way, at the lower angle of the wound (Fig. 2).

The next step is to separate the corpora cavernosa from their attachments to the rami of the pubes. It is generally recommended that this should be done with a periosteal elevator. The close attachment to the bones renders this a matter of considerable difficulty, and after separation there is a free hemorrhage which is difficult to control. The author prefers to burn through the crura penis with a Paquelin cautery close to their attachments to the bone and in this way the corpora cavernosa

a recurrence of the cancer will inevitably take place later on.

The writer has operated in the manner described in three cases. One patient, a man of advanced years, died from sepsis a week following the operation. In this case the operation was a protracted one, as the crura penis were separated from the pubic bones by means of the periosteal elevator, and the difficulties of freeing them from their attachments and afterwards of stopping the hemorrhage were very considerable. In the second and third cases the separation of the crura penis was accomplished with great facility by burning through their attachments with the Paquelin cautery.

The second patient lived a year after the operation and died of a recurrence of the growth in the healed scar of the wound.

The third case was operated on three months ago and the wound healed by primary union, but although the glands in the groin, which were enlarged and beginning to break down, were entirely removed at the time of the operation, a recurrence has taken place at that point and the progress of the disease is very rapid.

40 Schermerhorn St., Brooklyn, N. Y.

Fig. 4.—Operation as completed. Urethra sutured into wound, with sound introduced through it. Lateral flaps brought in apposition and retained by interrupted sutures.

are readily freed from the pubes and without hemorrhage (Fig. 3). The Paquelin can also be used to stop bleeding, which generally occurs from the dorsal vessels of the penis under the symphysis pubis, at the upper angle of the wound. The final steps of the operation consist in bringing the urethra up into the wound and stitching it to the margins of the skin flaps, and then the skin on either side is brought into apposition and stitched. A catheter may be carried through the urethra and left in the bladder to drain it (Fig. 4).

In this operation the testicles are exposed and may be left in the wound, or castration may be performed to quell the sexual desire on the part of the patient after his recovery. The inguinal lymphatic glands should be removed at the time any operation is performed for the relief of malignant disease of the penis, for if the glands have become infected, which occurs early in the disease,

#### MEDIAN PERINEAL PROSTATECTOMY: TOTAL REMOVAL OF THE PROSTATE GLAND, SIX CASES.\*

ALEXANDER HUGH FERGUSON, M.D., C.M.

Professor of Clinical Surgery in the Medical Department of the Illinois University (P. & S.); Professor of Surgery, Chicago Post-Graduate Medical School; Surgeon-in-Chief to the Chicago Hospital, etc.

CHICAGO.

There are so many different methods of treating prostatics that one is forced to the conclusion that the subject is in an evolutionary stage. I venture the assertion that every surgeon of experience has often been disappointed with many of the procedures he had employed. It is true that every case is more or less a special one, having individual features and combined phenomena of its own, but when we consider the radical treatment, that is, total prostatectomy, it should not take us very long to establish one method as the safest and best. The era of giving permanent relief to over 25 per cent. of the male population in the last third of life began in 1887, with first, Belfield of Chicago, and then McGill of Leeds, England. They did a partial and then as they improved their technique, complete suprapubic extirpation of the prostate gland. At the present time, through the combined efforts and experience of surgeons the world over, not forgetting to give a larger amount of credit to American surgeons, suprapubic total prostatectomy with a perineal incision for drainage is about as perfect as can be expected. I am surprised to notice that Mr. P. J. Freyer of London, England, in speaking of suprapubic prostatectomy, gives no credit to other surgeons for removing the entire gland by that method. In closing a lecture delivered by him at the Medical Graduates' College, June 26, 1901, entitled "A Clinical Lecture on Total Extirpation of the Prostate for Radical Cure of Enlargement of that Organ," he makes the following statement: "I think I shall not be accused of exaggeration when I state that all previous so-called methods of radical cure of enlarged prostate are unsatisfactory, and that catheterism, though the least objectionable mode of treatment in the vast majority of cases, is liable sooner or later to terminate in cystitis, or other danger-

\*Read before the Southern Surgical and Gynecological Society meeting held at Richmond, Va., November 12-14, 1901.

ous complications; I admit that the thoroughly successful results obtained in these four cases of total extirpation of the enlarged prostate encourage us in the hope that we have at last arrived at a rational method of dealing with this painful and frequently fatal malady."<sup>1</sup>

This is an illustration of a surgeon probably too busy to look up the literature on his own special subject. In accordance with our American text-books on genito-urinary surgery, let alone the most recent articles in medical journals, the claims of Mr. Freyer that, by his procedure, "we have at last arrived at a rational method," etc., come too late.

We have all been practicing it, and still we are not satisfied. The patient is often disappointed with the results. The dangers from shock, hemorrhage and sepsis by this method are not trifling; the mortality is too high; the discomfort from the suprapubic incision with sometimes a permanent fistula as a sequel, is objectionable; in a proportion of cases the bladder fails to regain its power of expulsion, especially when all the urine had to be drawn off by catheter before the operation was performed. The prostate is difficult of extirpation from above and when large masses are removed they overstretch the neck of the bladder and incontinence of urine may result. It must not be forgotten that the prostate is situated external to the bladder and it seems too bad that the latter should be attacked and injured in front and behind in order to deal with offending portions of the former. I shall endeavor to show that the entire prostate can be removed more quickly and safely through the perineum than through the bladder. Let me first briefly state what has been done by other surgeons in this line.

In 1895, six years ago, Nicoll of Glasgow removed the prostate through a T-shaped incision in the perineum. He did an intra-capsular enucleation with the fingers of one hand, while through a suprapubic cystotomy he made counter-pressure from above within the bladder with the fingers of the other hand. He packed the perineal wound with gauze, inserted a retention catheter through the urethra into the bladder, and closed the suprapubic wound.

In 1896, Alexander improved Nicoll's operation by performing a suprapubic and also a perineal cystotomy. He cut through the membranous portion of the urethra. After enucleation he drained both ways.

Guiteras performed a perineo-prevesical operation. He opened the space of Retzius suprapubically, through which he made counter-pressure on the bladder without opening it here.<sup>2</sup> Another method of Guiteras is the vesico-rectal method. It is objectionable to open the rectum and the same can be said of the prevesical space or bladder.

Syms<sup>3</sup> endeavors to aid perineal prostatectomy by using a rubber retractor with which he claims "to pull the bladder and prostate down into the perineum so that the lobes can be reached and enucleated with the index finger. This retractor consists of a soft rubber bulb, cemented to the end of a strong rubber tube of a caliber of 38 French scale. It is introduced into the bladder through an opening in the membranous portion of the urethra; the bulb is then distended till it has a diameter of  $2\frac{1}{2}$  or 3 inches." In this operation the membranous urethra is opened, which can be avoided by the method which I practice. The injury to this portion of the urethra is objectionable and the overstretching of

the neck of the bladder by means of the bulb of the retractor is, I am convinced, a serious procedure. Let me here quote his own words: "In two of the cases there was incontinence of urine for some weeks." In one case the patient regained control of his bladder, but in the other the incontinence is permanent, as is honestly given in a foot-note. This result to the neck of the bladder is exactly what might be anticipated from such a retractor. Powerful traction made on the retractor dilates the neck of the bladder unduly, and incontinence is the result. In connection with the literature of perineal lithotomy many cases of permanent incontinence of urine are recorded, following the forcible extraction of a large stone.

Figure 1.

Von Dittel, previous to Nicoll's operation, had several times successfully removed the prostate through an extra-vesical incision, beginning at the apex of the coccyx and going to the right of the anus in a semicircular manner. The dissection is carried along the side of the rectum to the prostate, etc. Several other surgeons have operated by this method. A crescentic incision in front of the anus has also been used, even for a partial prostatectomy, but in reaching the prostate undue destruction of the perineum was done. The most recent surgical text-books, Bryant's "Operative Surgery," for instance, state that "if the prostatic urethra be so much lengthened because of the prostatic hyper-

1. Brit. Med. Journal, July 20, 1901.  
2. Phil. Med. Journal, April 20, 1901.  
3. Journal A. M. A., Nov. 2, 1901.

trophy that the finger is not available for exploration purposes, this method (median perineal prostatectomy) of operation should not be practiced."

In the literature are found the writings of many surgeons in connection with partial as well as complete prostatectomy through the perineum. Chief among these are T. E. Bryant, Gouley, Eugene Fuller, Reginald Harrison, Mercier, G. Frank Lydston, R. D. Webb and H. H. Young.

By the method I am about to describe, all forms of prostatic enlargement are successfully treated.

#### OPERATION.

Put the patient asleep with chloroform and place him in the extra-lithotomy position; insert the prostatic depressor—Plate 1, (A)—into the bladder, through the urethra, and hand it over to a trusty assistant. Insert a sponge into the rectum to prevent escape of liquid feces. Then introduce the middle finger of the left gloved hand into the rectum and press it against the

them drags the gland still further into the wound and holds it firmly while enucleation and extirpation are being performed. It is experienced that by traction from below and depression from above, the prostate is fixed, within easy reach for its entire removal. Enucleate with the finger and bite away the portions thus liberated with the prostatic forceps—Plate 1, (B)—until by piecemeal the prostatectomy is completed. Small, strong, blunt hooks may be used to advantage to drag the gland down. No effort is made to save the posterior portion of the prostatic urethra; indeed, injury to it can not be avoided when the entire gland is removed. While morcellation is in progress, it is always advantageous to advance the retractors farther within the capsule and sometimes to introduce the middle finger into the bladder. The forceps can be rapidly thrust between the two fingers to the object to be removed, without any danger to surrounding structures, for when the instrument is closed, its end is perfectly smooth and round. The lateral lobes can be reached to any extent without damaging

Figure 2.

urethra at the junction of membranous and prostatic portions: pass a long narrow-bladed knife into the perineum through the raphe. posteriorly, two inches in front of the anus, until it reaches near the tip of the finger in the rectum and with one stroke cut through all the structures to the prostate without injury to the urethra, prostate, rectum or anal sphincter. Refrain from doing this in your first cases, but incise more carefully. Now enlarge the skin incision, if necessary, for the introduction of two fingers. Place suitable retractors—Plate 2, (A)—one on each side, into the wound, and by blunt dissection expose the prostate and with the depressor in the bladder force it into the perineal wound—Plate 2. Open the capsule with knife or scissors in a transverse direction sufficiently to admit one or two fingers. Place the retractors within the capsule. This is important, because traction made on

Figure 3.

the wall of the bladder, and prostatic projections of the middle lobe are detected and removed without difficulty. Flush out the bladder very thoroughly with a weak antiseptic solution. A large stream of water should be used, for the ordinary irrigating toy only does harm. Mop out with gauze any water that is in the bladder and wound and introduce a drainage tube—Plate 1 (C)—surrounded with iodoform gauze—Plate 3—through the wound into the bladder. A couple of stitches close the part of the skin wound not occupied by the tube and at the same time prevent the gauze from coming out too soon. Remove the sponge from the rectum, place a comfortable firm dressing over the perineum and retain it by a T-shaped bandage. Now attach a long rubber tube to the external end of the drainage tube, and the toilet of the operation is finished.

If the patient's urine has been scanty or should he

show depression or shock, then it is better to introduce two or three pints of normal salt solution, at a temperature not less than 115° F., beneath the skin while he is still in the operating room than to wait until he is taken to bed.

CASE 1.—Mr. W., aged 65, German farmer, was referred to me by Dr. Pratt, of Goodland, Ind., complaining of frequent, difficult and painful urination. Temperature was 101 F., pulse 96 and respirations 20. When he entered the hospital there was great desire to urinate, but he could not accomplish it. The urine, to the amount of 24 ounces, was drawn off through a soft rubber catheter with surgical cleanliness. In three hours he had a chill, vomited, temperature 102, pulse 120 and respirations 24. The bladder was washed out with boric acid solution, and 5 grains of urotropin given every four hours internally. The next day he was as well as he was when he entered the hospital. The urine drawn off contained a large quantity of pus, was acid, and had specific gravity of 1010. It was ascertained that his bladder symptoms began ten years previously. The painful urination only commenced three months before; complete retention occurred three times during the last six months. In brief, he had the symptoms and signs of prostatic obstruction, complicated with prostatocystitis. Seven days were occupied with preparatory treatment. He was given light diet, calomel, strychnia, urotropin, salines and enemata. The bladder was washed t. i. d. with a solution of chinosol, 15 grs. to the ounce of sterilized water. Each time, before the bladder was irrigated, he passed what urine he could, and was then catheterized. During those seven days the amount of residual urine averaged 18 ounces and he voided about 50 ounces in all during each twenty-four hours. It contained pyogenic germs, pus, bladder cells, no sugar and a trace of albumin. The temperature did not fall below 99 F. There was slight leucocytosis, no pain in lumbar region, and no tenderness elicited by prodding over the kidneys nor by palpation. He could not bear firm pressure over the bladder. Through the rectum I could ascertain that the lateral lobes were tender and very large; the one on the left could be felt bimannually. The preparation relieved him very much, and the quantity of pus was very markedly reduced. No cystoscopic examination was attempted, on account of the prostatitis and cystitis. His personal and family history was excellent. On Nov. 20, 1900, I performed a median perineal prostatectomy. The whole prostate was removed with ease; the portions projecting within the bladder were reached without any difficulty. Some sections of the organ were so adherent to the capsule that the finger could not liberate them, but these were snipped away with the cutting forceps. The aid rendered by the depressor was valuable when dealing with the central lobe, which projected into the bladder fully an inch; at one time the instrument was turned end downwards, behind the prostate, and traction made on it, which brought the central lobe into view. The bladder was now washed out and a cystoscopic examination made. There was no injury done to the bladder and the membranous urethra was not lacerated in the least, but the posterior portion of the prostatic urethra was taken away. The cystoscope was not of much use, except in seeing that the bladder was not traumatized. With my forefinger I could feel the large cavity from which the gland had been removed. He suffered no manifestations of shock whatever; had no vomiting; the highest temperature during convalescence was 99 F., and the highest pulse rate 98. The tube was removed on the seventh day. The perineal wound closed on the fifteenth day and he left the hospital on the 11th of December, 1900, just three weeks from the day of the operation.

Condition on Leaving: He was walking about, urinating six times during the day, and once at night. Had no pain or discomfort, no residual urine, was gaining in flesh, and felt happy. A few pus cells and bacteria were still in the urine, and a trace of albumin. There were no casts. He reported two months later that he was working on his farm, had no trouble in urinating, no pus and no albumin in the urine. Report six months later from Dr. Pratt: Mr. W. died suddenly of angina

pectoris. He was working at the time; had not complained of bladder symptoms.

CASE 2.—Mr. B. B. F., aged 69, also referred by Mr. Pratt, of Goodland, Ind., entered hospital Dec. 6, 1900, with a letter stating his exact condition. He complained of inability to pass water freely; the onset was tardy; the stream was slow, painful, and urine dribbled. The quantity of urine, passed the first twenty-four hours, was only 12 ounces; it was acid, dark-brown in color; specific gravity 1021; urea 2.5 per cent.; albuminous, contained blood, pus and cylindroids. The frequent urination began to be troublesome five or six years ago. His personal and family histories were very good. In order to increase the quantity of urine and to improve its quality, all the water possible was administered by mouth, rectum and subcutaneously. He improved every day; at the end of a week he voided 68 ounces of urine, but it still contained pus and albumin. During preparations the residual urine varied between 7 and 16 ounces. The bladder was irrigated twice a day; urotropin and strychnia were given three times a day. With the attention given so comfortable did he become that he almost backed out of an operation. The prostatic urethra was two inches longer than normal. The left lobe could be felt per rectum to be enlarged. With the cystoscope I could see the central projection and the tumor formed by the left lobe quite distinctly. The redness and granular appearance of the inflamed prostate were very distinct.

On Dec. 14, 1900, I performed a median perineal prostatectomy and removed the entire left and median and about two-thirds of the right lobe, although it was normal. There was no shock. The next day his temperature was 100 F., pulse 70, and respiration 22. The second day the slight fever had subsided. On the fifth day the tube and gauze were removed and replaced. On the sixth day temperature was 102, pulse 78, and respiration 24. The gauze and tube were removed and left out, after which the constitutional disturbances subsided. On the seventeenth day the wound closed and much to his delight he passed his urine per vias naturales. By this time it had increased to 8 ounces, but it still contained some pus and a trace of albumin. He left the hospital Jan. 9, 1901, twenty-six days after the operation. He was then passing his urine every three or four hours, during the day and twice during the night. A cystoscopic examination revealed a slightly reddened portion of mucous membrane at the neck of the bladder. Five months after leaving the hospital he came alone to Chicago with a carload of cattle and called to see me. He stated that he was a new man. This gave me an opportunity to see him pass a full stream of urine, with that ease and comfort which might be envied by a younger man. On passing a catheter, no residual urine was there; this specimen of urine was normal. This gentleman never had used the catheter, but his physician had passed it for him occasionally the last couple of weeks before coming to the hospital.

CASE 3.—Mr. C. W. G. entered the hospital March 15, 1901, accompanied by Dr. Wagner of Tacoma, Wash. He was complaining of inability to urinate naturally. The act of urination was slow, difficult, sometimes painful, and often impossible. The time occupied was often from twenty minutes to half an hour, and repeated efforts not infrequently were futile to pass any at all; then the catheter had to be used. He has had to get up six or eight times during the night; three hours is about the longest time he could go without trying to urinate. The quantity passed each time varied, but often only about an ounce was voided. He had had two years and a half of catheter life. It is four years since his bladder trouble began. He remembered going to Victoria, B. C., to play golf, and held his urine too long, and after the game was over he had trouble to urinate. At that time the urine came slowly and only with considerable effort; for a few years before this he had to get out of bed at night once or twice, but thought nothing of it and after this he had more or less difficulty. He was steadily getting worse. In the fall of 1899 the prostate was enlarged with sounds of a suitable curve. In October, 1899, inflammation of the bladder and prostate nearly ended his life. During this illness he lost 50 pounds and a slough of prostatic

tissue came away. He then improved. Although he has had several attacks of irritation of the bladder, prostrating him for several days at a time, still he has had none so severe as in October, a year ago. His personal and family histories are excellent.

**Physical Examination:** He was passing only 30 ounces of urine, which contained pus, etc. Residual urine was 12 ounces. In four days this quantity was increased to 70 ounces, but residual was just the same. Urea, 1.2; specific gravity, 1014; contained pus; acid reaction. I made two cystoscopic examinations in this case, one two months before he came for operation, and again after he entered the hospital. The instrument passed into the bladder without difficulty each time; there was a deep groove posteriorly where the middle lobe had been, and from which it had sloughed away, as already mentioned. The prostatic urethra was nearly normal in length, but two large tumors could be seen closing the canal as the cystoscope was being removed. There was no cystitis and I feared the pus came from one of the kidneys, but fortunately it did not. The central groove simulated that left after a Bottini operation, but was much deeper and wider. Here was an excellent proof of urinary obstruction, caused by enlarged lateral lobes. By a rectal examination the hypertrophy did not feel to be excessive, although the size of two hens' eggs. On March 19, 1901, the operation was performed and the two large lateral lobes and what was left of the central were removed. Patient suffered practically no shock. He vomited a few times after the chloroform. The tube and gauze were removed on the fourth day. Bladder control was regained on the tenth day. At the end of two weeks he went out driving, the next day his left testicle was swollen and tender. The orchitis (not epididymitis) did not subside for ten days. On the twentieth day urine ceased to come through the perineum. The wound was reopened twice thereafter, and then it closed permanently. It was six weeks before he left the hospital, at which time a few pus cells could be detected in the urine, but he completely emptied his bladder, without pain or inconvenience. Reports since are to the effect that he feels as well as he ever did.

**CASE 4.**—Mr. M. A. Perry, Iowa, age 51 years, referred by Dr. Mereer of Chicago, entered the Chicago Hospital on April 3, 1901, complaining of: 1, frequent and painful urination; 2, inability to work; 3, disturbed every hour or two of the night, and 4, a sudden stoppage of the stream occasionally. He suffered most excruciatingly. It was distressing to witness him having what he called "spasms." The pain in the bladder was constant and severe, but that in the urethra and at the glans penis was much worse. His trouble began eight years ago with symptoms of stone in the bladder. The last year attacks of pain and fever would confine him to the house for days. The last two years he passed small uric acid calculi off and on, which he carried in his pocket. The urine has been scanty for three years. He was now passing 64 ounces and there is 11 ounces of residual; specific gravity, 1020; urea, 1.5 per cent. Blood, pus, albumin and indican are present. Thompson's stone-searcher was passed, and the stones felt and the clicking sound heard as they were tapped by it. Examination through the rectum was negative; no enlargement of the prostate could be felt; but the large amount of residual urine indicated obstruction. At the end of four days he was ready for the operation. He was then chloroformed, and cystoscopic examination made. The middle lobe protruded into the bladder. It was pear-shaped, and inflamed. It was with some difficulty that the stones could be seen by direct view. On April 7 I did the median perineal operation and removed the whole prostate and six stones. Although the lateral lobes were not much enlarged, I thought it wise to remove them, to prevent further trouble. He suffered so much with spasms at the neck of the bladder, after the operation, that morphia had to be given freely. On the third day I removed the tube with the hope of relieving him, but he suffered with the spasms four days longer. He passed his water naturally on the fourteenth day and left the hospital on April 30, 1901, in excellent spirits and health. There was no residual urine then; pus was still present. October 10 last he presented himself to show me how well he was. He was completely cured; urine normal, etc.

**CASE 5.**—Mr. P. C. H., aged 69, entered Chicago Hospital on April 19 1901, complaining of difficult and painful urination. The quantity of urine varied from 30 to 60 ounces, of low specific gravity, 1002; urea less than one per cent.; contained blood, pus, and hyaline casts. Passed from 2 to 4 ounces at a time. On account of some fever (99 F.) and general weakness, he was in the hospital for twelve days before operation; during this time the pyrexia continued. Difficulty in urinating began sixteen years ago (1885), which he attributed to horseback-riding. In 1893 cystitis came on, and he has not been well since. The last year he expertly catheterized himself. He had several attacks of double epididymitis, and is now suffering from a chronic hydrocele that has been several times injected.

Operation was on April 30, 1901. Through the perineum I made a very sweeping operation of the whole prostate gland in a very few minutes. The gland protruded in all directions. It could be outlined bimanually as a huge mass in the pelvis, the left lobe extending upwards into the bladder, so as to be palpable. The prostatic urethra was two and one-half inches too long. The central lobe was nodular, three large nodules extending from it into the bladder. A more difficult case could not have been selected to test the scope of my procedure via the perineum. I also operated on the hydrocele. The tube was removed on the fourth day. On the twelfth he sat up in a chair. Perineum closed on the twentieth day. He left the hospital on the thirty-third day after the operation. He has written that he has not been so well for years. When he left for home the urine was free from pus.

**CASE 6.**—Mr. A. M., age 72, carpenter, referred by Dr. Alexander, presented himself on March 12, 1901, complaining of incontinence of urine. He was wearing a rubber urinal to keep himself dry. In 1888 frequent urination and night disturbances began. For six years he managed to bear with his "weakness," as he called it. In 1894, after drinking too much spirits, and after going home about 12 o'clock at night, he failed to micturate. Towards morning he became so distressed that a physician was called. He catheterized him. On two other occasions within a year the physician drew off his urine. In the intervals, outside of frequent acts, he felt all right. During the last two years he has been using a catheter somewhat carelessly, but without infecting himself. It was a silver catheter, No. 6, of English make, with a good curve. It was never boiled. He simply washed it with soap and water after using it, blew his breath through it and put it back into an old leather case. He declared that before using it the desire to urinate was so urgent he simply smeared vaseline or lard over it and then relieved himself. Three weeks ago the urine began to dribble. It made him uncomfortable, so he bought the urinal. Since then he has only used the catheter about once a day. In the interim he allowed the urine to escape into the urinal.

After he had urinated two ounces I passed the catheter and withdrew 36 ounces of almost normal urine. I was surprised at this because of the careless manner in which he used the catheter. Its specific gravity was 1018; straw color, urea 1.5; no pus, blood or bacteria, nor casts, albumin, nor sugar. He said that years ago he had passed some blood once or twice, but since he had learned to use the silver catheter his urine has been clear and normal in color.

On March 15, 1901, I removed through the perineum the two lateral lobes, hypertrophied to about the same extent, being about two inches in their longest diameter. On the third day I removed the drainage tube from the bladder. He urinated through the perineum for a week when about one-half the urine began to come through the penis. At no time did I deem it necessary to wash out his bladder. On the twentieth day after the operation the perineal wound was closed permanently, but it took him over an hour to empty his bladder. In the course of two months the contractile power of the bladder markedly improved and it did not then take him over twenty minutes to empty his bladder, but still the abdominal muscles had to be used and he had to strain in order to void all the urine. November 5, 1901, this gentleman is well and happy,

passes his urine normally, but it is diminishing in quantity, according to his judgment. He stated that he knows the quantity is less, but did not think it necessary to measure it.

#### ADVANTAGES OF THE OPERATION.

1. It is the most direct route to the prostate.
2. Injury to the bladder is avoided.
3. The operation can be quite easily performed. Even in those cases where the gland has been repeatedly inflamed it is not as hard to remove it from below as from above.
4. It is an advantage to remove the gland piece by piece for it enables the surgeon to work through a small opening without bruising the surrounding parts by the finger or a blunt instrument.
5. Hemorrhage is avoided so long as one is careful to work within the capsule. The hemorrhage in suprapubic prostatectomy or in the combined method is often very alarming. On one occasion the writer had to leave pressure forceps on bleeding vessels and pack the bladder tightly with gauze for twenty-four hours. The patient narrowly escaped death from both hemorrhage and sepsis. Sepsis and intoxication from pus and fetid urine coming in contact with the prevesical tissues and wounded and raw surfaces within the bladder are sources of great danger in the suprapubic operation. The bladder may be opened in two stages, it is true, and the prevesical space thereby greatly protected; but the traumatism of the bladder over the prostate, even though done with a cautery knife, furnishes an opportunity for sepsis.
6. Perineal drainage is more complete.
7. The danger from septicemia is not at all prominent after perineal prostatectomy, and so far has given no anxiety whatever, whereas more or less absorption of septic material is the rule in the suprapubic operation.
8. There is less danger of uremia. The operation consuming less time; the short anesthesia affects the kidneys less and there being a minimum opportunity for sepsis there is less work for the kidneys to perform. Uremia is always to be dreaded regardless of the operation.
9. The perineal operation is accompanied by far less shock than the author has noticed following suprapubic prostatectomy.

While not unmindful of the fact that but six cases are here reported, still the results obtained in these six cases have been so satisfactory that I am encouraged to continue this method of operating and also feel justified in recommending it to the profession.

Additional work on the prostate for hypertrophy of the middle lobe alone may be justly mentioned. In four cases, two complicated with vesical calculus which I crushed, the central pathologic lobe was removed through the median perineal section. In four other cases, viz., tuberculosis of prostate, which had extended to it from the epididymis on each side, I removed the gland entirely through the median incision. In these cases the testicles were preserved. Through an incision in each inguinal region the epididymis and testicles were pulled up, the former carefully separated from the latter, the internal inguinal ring enlarged, the vas deferens followed to the base of the bladder, and by blunt dissection a through-and-through communication with the perineal opening was obtained, which enabled me to extirpate the whole diseased track on both sides.

Double inguino-perineal as well as vesico-perineal drainage is necessary in those cases.

#### FRACTURE OF THE METCARPAL BONES, AND OBLIQUE FRACTURE, SIMPLE OR COMPOUND, OF THE FOREARM.\*

W. W. GRANT, M.D.

DENVER, COLO.

The functional results in the treatment of fractures are, in the main, so good that we can not hope for much better, without material improvement in the methods of treatment. The time has come when we must give more thought and consideration to anatomic results and appearances, regardless of the excellent results in useful limbs obtained by present methods. The *x-ray* has demonstrated this necessity, which overrides the argument of mere utility. Though the skiagraph may exaggerate and distort, yet, in honest and capable hands, it gives a fair illustration of the position of the fragments and with the aid of the fluoroscope, no serious mistake need be made. More accurate adjustment and coaptation of fragments is a manifest necessity, not only for the patient himself, but in a medicolegal sense to the surgeon. This is specially true in the treatment of oblique fractures of the long bones, and of special moment and consideration in the management of oblique fractures of both bones of the leg and forearm. Knowing that inflammation and complications incident to fractures of the forearm are more common than elsewhere, we also can not forget that rotation, affecting as it does, the future usefulness of the arm, is always involved. These considerations lend additional interest to these injuries. Despite union with much overlapping and displacement, or bony union of one and non-union of the other, good functional results are common, with no disfigurement in the outline of the limb; yet we can not be content with this result and condition. If the surgeon does not protect his reputation by every safeguard, the *x-ray* will destroy it in the courts if he treats many fractures—now the most dangerous field to the surgeon.

If the *x-ray* reveals what the educated senses and manipulation of the surgeon will not, and this is sometimes the case especially in fleshy subjects and fractures in the middle and upper third of the tibia and fibula, what is the remedy? If effusion of blood and lymph are, as Lane asserts, the chief obstacles to reduction and coaptation of fragments, then it is true that nothing short of operation by wiring, nailing or fixation by some such contrivance will enable the surgeon to thoroughly adjust and fix the fragments. There can be no question that blood and lymph do play important parts in the malposition of fragments. To this extent the application of splints, bandages or plaster will not correct the displacement; and extension, if delayed, will not be of much use. So whatever method is adopted, whether operation or the ordinary application of splints and extension, it should be used promptly. Delay, with the action of blood, lymph and muscular action, tends only to maintain the fragments more rigidly in the position left by the force of the offending agent. The action of the muscles, it seems to me, is under-estimated by Lane, while probably over-estimated by others and the influence of blood and lymph under-estimated. The fact remains that the ordinary treatment of oblique fractures of both bones of leg and forearm by splints, box, plaster, silicates and extension, are often very unsatisfactory, as is the case in similar treatment of fractures involving the elbow joint.

I know of no other procedure short of wiring, nailing

\* Read at the Western Surgical and Gynecological Association, Chicago, Dec. 18, 1901.

or the application of some fixation device directly to the fragments that will insure more perfect results. If either fibular fragment in any part is forced against the tibia, with or without a fracture of the latter, will any manipulation or force short of direct application to the fragments restore them to their proper place in apposition? I believe not; yet the outward contour and functional results may be satisfactory to the surgeon.

How would the ordinary Pott's fracture, as treated, look under the fluoroscope or in a skiagram? Doubtless it would not appear very pleasing in its axial line and its relation to the astragalus.

As to oblique fractures of the forearm, extension is not ordinarily used. If compound, the fragments should be wired or nailed. If not compound, continuous extension should be applied, or the bones should be treated by direct fixation. The latter has the advantage of not necessarily confining the patient to the room. Effective continuous extension does confine him, and it should

be maintained ten or fifteen days. We hesitate, quite naturally, to resort to the operative treatment, even with all the best aseptic agencies at hand, as long as fairly satisfactory results are obtained by other means. We can not, too, be unmindful of the fact that without the ordinary text-books and teachings to support us, we are in law and practice exposed to the dangers always incident to new and unfrequented paths. Yet without courage and the force of individual conviction progress is not possible.

I have nothing new in principle to present. It is but the application of Buck's extension in the treatment of fractures of the femur, to fractures of the forearm and hand. The method is equally appropriate in certain inflammatory conditions of the wrist and elbow joints. My attention was first directed to the matter in a desperate case that came under my care on July 4 last: The National Guard in camp at Boulder was firing a salute with 6-pound brass cannon when the premature discharge of a gun completely lacer-

ated the soft tissues of the left arm of Corporal P. from shoulder to hand, and also badly lacerated the right hand from the palmar surface and front of wrist. The little finger was torn off at the second joint, and its metacarpal bone was fractured in two or three places, completely detaching the proximal half. The second and third metacarpal bones were fractured near the metacarpo-phalangeal articulations: the third had a second fracture near the proximal end, and the fourth metacarpal also near the wrist was fractured: the ulnar artery was severed at the wrist, and the pisiform and cuneiform bones so badly damaged that they were removed. The thumb and first metacarpal were the only parts connected with the hand that were not badly damaged. I was on hand promptly and by the quick application of a rubber tourniquet around axilla and shoulder stopped the severe hemorrhage from the left arm. His left side was extensively and deeply burned, and face and eye were burned badly and powder stained. By the use of saline infusions with strychnin and external heat, reaction was sufficient in two hours to justify operation. Under heart tonics and the continuous subcutaneous infusion of normal salt solution while operating, I promptly amputated left arm at shoulder. With the compound comminuted fractures of right hand and badly burned and lacerated tissues, which were infiltrated with foreign matter, I could not expect the hand to escape infection. The bones were adjusted as well as possible, but to retain them in position, and therefore in respectable form to the hand, was, at the time, impossible. It was not safe to prolong the operation. So the badly damaged carpal bones and half of the fifth metacarpal were removed, vessels ligated, and the hand dressed and drained with iodoform gauze between loose splints. Hot water was applied continuously for ten days. Suppuration ensued and finally the middle flexor tendon, which was badly lacerated, and some of the fascia sloughed. At the end of two weeks I made incisions over the fractures of middle and index metacarpals near the phalangeal joints, as the greatest disfigurement existed at these points, and fastened the fragments with silver wire. The bones were soft, and, in order to hold all the parts in as good shape as possible (splints and bandages being practically useless), I applied the following extension apparatus to the fingers (index, middle and ring): Moleskin plasters, the width of the fingers, were applied back and front, all passing in a loop through a triangular ring (with a horizontal bar) about two and one-half inches in diameter, and each finger bandaged separately. (These are fortified by a wide piece of plaster covering all.) A small cord is tied to the ring and carried over a small pulley screwed into the ceiling lath. Three 1-pound weights were attached by a small iron hook to the distal end of the cord. Counter-extension may be applied by bandaging the arm to the body, commencing with a loop of bandage around the arm just above elbow and passing at first backwards around the body. With this arrangement the patient could lie down, sit or stand, and the extension will not vary a particle. If desired, the arm can be fixed by bandage to the bed frame. Splints, with antiseptic gauze drainage to the palm, were lightly applied during the treatment, which was maintained for two weeks and was easily borne. For fracture of forearm wide strips of plaster should be applied to back and front of hand and through the ring as before. In this case my aim was not only to save the hand, but to preserve its form, with as much motion as possible to the fingers. I am gratified to state that the thumb, first

metacarpal and wrist motions are perfect, and there is some movement to index and ring fingers, with promise of more. The flexor sloughed, and the others are necessarily crippled by adhesive inflammation. Had the other hand and arm been intact there would have been great temptation to amputate this hand; but in this day of bold and radical surgery, conservatism, too, achieves its greatest triumphs, which splendidly justifies the greater labor, time and skill devoted to it. Although the hand suppurated rather freely and there was extensive sloughing of the skin on left side from shoulder to waist line, which, with the hand, healed slowly, there was no general infection at any time. The patient at this time is in very good condition, and has one good arm and a fair hand, and will become again self-supporting.

I am aware that ambulatory extension to the forearm, with the lower part of the humerus as a fulcrum, is sometimes made or attempted, but I doubt if efficient, continuous and comfortable extension can in this way be satisfactorily carried out.

### THE QUESTION OF SPINAL BRACES IN LATERAL CURVATURE.\*

A. B. JUDSON, M.D.

NEW YORK CITY.

It has been proposed that apparatus having a strong antero-posterior action for the maintenance of lordosis be used, instead of braces which make the customary pressure on the ribs, in lateral curvature of the spine. Experiments in this direction have, however, resulted in nothing notable, and the suggestion has been fruitless so far as I am aware. It may be that the inconvenience of wearing such a brace is too great in a disease which carries with it no menace to the patient's life and but little to her health and comeliness. It might be argued, but not too seriously, that lateral curvature of the spine is an attractive feature, falling in the same category as a slight east or squint, which has been thought to add piquancy to the beauty of a pretty face. It can not be denied that the typical sigmoid curvature reproduces the technical curved line of beauty or that the accompanying rotation carries with it an expression of serpentine or sinuous grace.

It is true that in rare instances the rotation is so extreme that the kyphos rivals that of an ill-treated case of Pott's disease. As a rule, however, the deformity is not conspicuous and we are generally satisfied with the results of treatment which is palliative rather than radical. In Pott's disease the forcible production of lordosis transfers compression from the vertebral bodies to the processes, which as a rule are healthy. The same force in lateral curvature produces the same effect, taking superincumbent weight from the bodies which depart from, and putting it on the processes which are held near, the median plane. This provides a mechanical application directed against rotation, which is the most intractable element of the deformity.

Such may never be the established treatment, but an appreciation of the mechanics involved makes clear the fact that rotation is produced by the lateral mobility of the anterior section of the column combined with the absence of such mobility in the posterior section.

An interesting contribution to the study of this subject is the suggestion that rotation in lateral curvature may be determined by the flexion or extension of the spine. As an aid in this inquiry I arranged for photog-

raphy an imitation of the spine, made of India rubber, Fig. 1, in order to see whether antero-posterior variation would influence rotation in any way. The middle pin is taken point blank in each photograph in order to secure the same point of view in each exposure. In Fig. 2

Figure 1.

Fig. 2.

Fig. 3.

Fig. 4.

there is a plain lateral curve without flexion or extension. The heads only of the pins are seen, showing the absence of flexion, extension and rotation. In Fig. 3 a lateral curve is combined with flexion. The latter is shown by the inclination of the pins and the absence of rotation is demonstrated by the fact that the head only of the

Figure 5.

middle pin is visible while the heads of all the pins are found in the middle of the curved column. In Fig. 4 a lateral curve is combined with extension as is shown by the inclination of the pins. Some rotation is apparent, but this would have disappeared if the object had been

\* Read before the American Orthopedic Association, June, 1901.

placed more carefully before the camera so that only the head of the middle pin had been exposed.

From this it would appear that rotation of the spine is unaffected by its flexion or extension, a result which might have been expected *a priori*, because the curve in any case is but a simple curve and incompetent, as such, to govern rotation. In Figs. 3 and 4 the curve may at the first glance seem to be made up of two curves, a lateral and an antero-posterior one, but further consideration leads to the view that it is a simple curve, produced by the resultant of two forces, one acting in an antero-posterior and the other in a lateral plane, and as such it has no more power over rotation than any other simple curve.

It may be said that any rod or flexible column can not, of itself, rotate when curved. The spine, however, is a flexible column, a part of which, made up of the vertebral bodies, has wide lateral displacement (or has extra flexibility) in the cavity of the trunk; while another part, composed of the processes, is prevented from lateral

Figure 6.

displacement (or has less flexibility) from being a constituent part of the wall of the cavity. It, therefore, rotates when curved. This view was presented by Mr. Charles H. Rogers-Harrison in 1842.<sup>1</sup> The mechanics of spinal rotation thus described in words is shown in the common preparation of the vertebral column, Figs. 5 and 6, in which the processes are held near the median plane by a succession of spiral wire springs, while the bodies, swinging away from the median plane, exhibit rotation.<sup>2</sup>

The application of posterior pressure is demanded by the mechanics of the deformity which, on the other hand, furnish no warrant for the use of a brace making lateral pressure at the ribs. Such a brace may promote comfort and conceal asymmetry, but if it is applied with force it will add to the deformity. As the ribs spring from the posterior section of the column, pressure on them will

push the spinous processes still further towards the concavity and thus increase the rotation, as was pointed out by Mr. Andrew Dods<sup>3</sup> in 1824. The difficulty may be readily appreciated by imagining the effect of lateral pressure made directly on the vertebral bodies without the intervention of the ribs. The effect of such an application, impossible as yet, would be to combat, by one motion, both the lateral curvature and the rotation, at once correcting the deformity in simple cases in which structural changes were absent.

## THE REPORT OF A TYPHOID EPIDEMIC AT THE IOWA STATE AGRICULTURAL COLLEGE.

W. E. HARRIMAN, B.S., M.D.  
AMES, IOWA.

This epidemic occurred at the State College of Agriculture and the Mechanic Arts, at Ames, Iowa, in the fall of 1900. The total number of cases was 65. Of this number 23 went to their homes at the onset, or early in the disease; 42 remained to be cared for at the college—males 33, and females 9.

*General Environments.*—The college is located one and one-half miles from the town proper. It is situated on a 1000-acre plot of high rolling land, provided with most excellent natural drainage, abundant exposure to sun and wind, and altogether one of the most naturally healthful spots in the state. The buildings are large and well constructed, and fitted with first-class water supply, plumbing and sewage-disposal—in short, they are in good sanitary condition.

The enrolment of students at the time of the outbreak was about 900. Many of them roomed at the various college dormitories. Margaret hall, a building devoted to the lady students, contains also the large college dining-hall. Most of those students who roomed in college buildings and a few additional students and faculty assistants took their meals at this dining-hall. Of those remaining, some lived in the dormitories and dined outside the college; others both roomed and boarded entirely off the campus in private residences near the college or in the town proper, but all used the one water supply, closets, etc., while on the grounds.

This definite knowledge of the whereabouts and customs of the entire student body rendered possible a systematic study of etiologic factors and warrants a somewhat detailed narration of the events which led to the discovery of the source of infection.

When it became apparent that the college was in the face of an epidemic there was instituted a renewed study of the existing sanitation and a determined search for the origin of the disease. The problem was approached from the following vantage grounds: 1, sewers and sewage disposal; 2, water supply; 3, food supply; 4, all other possible sources.

*Sewers and Sewage Disposal.*—The closets of the various buildings, the laboratories, the creamery, the laundry and kitchen in Margaret hall, as well as many of the faculty residences, are connected by individual outlets with the main sewer. The sewers are of the most approved sewer tile, comparatively new, and were constructed under the direct supervision of most thoroughly competent sanitary engineers. The plumbing is of the best; modern ventilated traps are used throughout, and are supplied with arrangement for abundant flushing. It has been the custom during the college term to give the sewers an extra flushing at least once a week. The

2. Transactions New York Academy of Medicine, 1876, pp. 315-330.

system was inspected without the discovery of any defect whatever. No leak could have existed without detection owing to quantitative measurements of the sewage and other sewage experiments which were then in progress.

*The sewage-disposal system* is that known as the septic tank and intermittent filtration process. This is the most modern and satisfactory system in use to-day. It is so successful that after the sewage has passed through the septic tank and through the bacterial filter beds the effluent can scarcely be told by its appearance from the clearest sparkling well water. The principle upon which the plan depends entails the process of septic precipitation and bacterial consumption, combined with simple filtration. This plant was in the most perfect condition and was heartily approved by Dr. J. F. Kennedy, of the State Board of Health, during his inspection of the entire college premises.

*The College Water Supply.*—The water is pumped from a well 2215 feet deep into a large, tightly closed steel tank, 168 feet above the surface, and is piped to the various college buildings and residences on the campus. The tank, when filled, contains 160,000 gallons. The daily consumption of water is 90,000 gallons. So that if the tank were completely filled the regular demand would exhaust the supply in less than two days. However, as a rule, the tank is kept about half full. Hence, practically each day's supply is freshly drawn from over 2,000 feet below the surface. When the tank is half filled there is a pressure of 60 pounds to the square inch in the mains. Had there been even such a misfortune as a leaky main passing through a bed of typhoid bacilli, the water would have found constant exit through the leaks with such force as to have positively precluded the possibility of bacillary entrance.

The water had been examined each year and always found in good condition. But, not content with this and the above negative evidence, it was again subjected to thorough chemie and bacteriologic tests, and found to be in an exceptionally high state of purification. These analyses were made by Prof. J. B. Weems, of the department of chemistry, and Prof. L. H. Pammel, college bacteriologist, and were confirmed by Prof. Macy and Dr. Grimes, respectively chemist and bacteriologist of the Iowa State Board of Health. Failing to locate the difficulty in the college water supply attention was called to the

#### BOARDING DEPARTMENT.

Here nothing leading to a clew was discovered, until in the investigation of food and its sources there was reached the important item of milk.

*The Milk Supply.*—At the beginning of the term the college had contracted with one Skelton and one Pritchard (farmers near the college) for the necessary supply. But on September 2 Mr. Skelton's supply having practically failed, he arranged with one Mr. Briley (another farmer) to make good the deficit. Mr. Briley did so and in large amounts from September 3 until October 17, the greatest amount having been delivered during the week from September 15 to 24. At the mention of the Briley milk the recollection at once occurred to the author of the existence, nearly all summer, of a severe and prolonged case of typhoid in the family of Mr. Briley. The case occurred in the practice of Dr. C. S. Hutchinson, of Ames, who assured me of the correctness of diagnosis. Acting upon the suggestiveness of this coincidence the Briley milk was rejected in toto, and all other milk subjected to pasteurization prior to its use. Investigation was further continued, but it is very inter-

esting to note in this connection that the last case was bedridden November 3—three days less than three weeks (usual limit of period of incubation) from the date on which the Briley milk was condemned.

*Additional Water Examinations.*—Specimens of water were obtained from Skelton's, Pritchard's and Briley's wells—the latter having two wells. Both chemists and bacteriologists pronounced all the specimens free from suspicion except the shallower one of the two Briley wells. This water is said to have contained over 180,000 germs to the cubic centimeter—among them a bacillus somewhat resembling Eberth's bacillus—if not that identical organism, it was at any rate a member of the typhosus group. Regarding the chemie conditions of this water, Professor Weems reported as follows:

The Briley wells, two in number, are situated about four feet apart, one having a depth of 180 and the other 45 feet. The 180-foot well showed chemically to have water of excellent quality. The shallow well is, on the other hand, evidently contaminated from some source. The excessive amounts of nitrogen as nitrates and nitrites, and also chlorids would indicate that some vault or outhouse was the cause of contamination. The results also indicate that a large amount of the organic matter in the original source of contamination had been oxidized by the process of nitrification. The water was in worse condition than the effluent of the college sewage beds.

From a chemical consideration of the matter the conclusion of the investigation shows that the Briley shallow well is evidently the cause of the trouble, as it probably is in connection, by some underground means, with a vault. It would naturally result that should typhoid bacilli be introduced into the vault or outhouse the underground connection would transmit them to the well readily through the casing of the well; and the use of this water for washing the milk cans and watering the milk would transfer the germs to the individual using the milk.

Mr. Briley admitted that he did not scald the milk cans; hence, if bacilli were present in the wash water nothing hindered their development in the cans.

*Further Facts Regarding the Milk.*—The milk collected in these unscalded cans was delivered at the college once each day, about 8 or 9 a. m. It was kept all day and served for supper, thus allowing an abundance of time for the development of bacilli. Owing to its tendency to sour easily it was kept separate from the other milk. The cook drew from this supply for cooking purposes, but the greater portion remained to be served first for supper. The dining-room contained 61 tables, with 8 persons per table, making the total of 488 people in the dining-room served at the same time. Three pounds of milk were served to each table, except Nos. 58 and 59, the patrons of which received a double portion, six pounds each. These were known as the training tables, being patronized by sixteen football men in training. These students were encouraged to use their double portion of milk, and it is a painfully significant fact that thirteen of those sixteen powerful fellows contracted typhoid.

Some of the Briley milk reached various parts of the room, but a greater portion was distributed in the west half, and a greater number of cases occurred among those of that end. The younger students, many of whom were recently from rural homes, occupied this section, and being accustomed to the use of milk at home as an acceptable food, doubtless drank more than the older students. There were no cases among those who did not drink raw milk, and in every instance of sickness, upon interrogation regarding the milk, the patient replied that he had drank milk freely. Whether the Briley well

water contained the organisms and the milk became in this manner infected, or whether by flies passing from the dejecta to the milk cans in a tank near by will never be positively known because of the unfortunate destruction of the bacteriologic laboratory and its contents by fire. Isolation experiments with the milk and with the Briley water were in process when the disastrous fire occurred in the main building and destroyed all cultures and further means of determining the exact method of infection of the milk. But in the light of the above facts there can be no reasonable doubt as to the infectiousness of the milk from whichever of the two sources it may have originated.

*General Management of the Epidemic.*—The college is provided with a very satisfactory little hospital for the care of its sick. But, unfortunately, at the time of this epidemic the building was not habitable owing to extensive repairs then in progress. We had a small tent which was in use as a temporary hospital, and into this were taken the first few victims. But new cases developed rapidly. We were compelled to leave many of them in their various rooms to the care of their already over busy room-mates until suitable quarters could be obtained. Upon October 15 we procured a large recitation-room in the Agricultural building. All furniture was removed, floors scrubbed and patients installed with great dispatch. Nurses were procured, and with this unorganized, unfitted arrangement our epidemic continued to swell. Between October 8 and 17 there occurred 46 cases, 33 of whom remained to be cared for in our improvised hospital. The other 13 went to their homes. From this time on the number of new cases grew less rapidly till by November 3 the last case was bedridden and the total number had swelled to 65—of whom 42 were in our hospital.

The actual disease was severe and the demand for medical attention on the part of the genuine cases and the "psychologic typhoids" was so great that it became necessary to procure assistance. Accordingly, the services of Dr. C. G. Tilden (now of Stanhope, Iowa), were procured.

*Diagnosis.*—The 42 cases treated at the college occurred in the following sequence:

|          |                  |
|----------|------------------|
| October  | 8, three cases.  |
| "        | 9, one case.     |
| "        | 10, two cases.   |
| "        | 11, four cases.  |
| "        | 12, seven cases. |
| "        | 13, two cases.   |
| "        | 14, three cases. |
| "        | 15, seven cases. |
| "        | 16, three cases. |
| "        | 17, one case.    |
| "        | 19, two cases.   |
| "        | 20, one case.    |
| "        | 24, two cases.   |
| "        | 27, two cases.   |
| November | 3, two cases.    |

There was some hesitancy in the first three or four cases, but the diagnosis was practically forced upon us within a few days by the continued daily development of new cases. The usual history of insidious invasion was characteristic of all cases in this series. Headache with slight elevation of temperature, noticeable body soreness, and general malaise were common to almost every case. Epistaxis was present in about half the cases, constipation was the rule with two or three exceptions. Confinement to bed, enlargement of the spleen, and the steplike temperature were noticeable in a vast majority within a week of their first report of illness. The splenic involvement was more generally present here, I believe,

than is usually the case. The appearance of rose spots was wonderfully constant, and there were cases in which this phenomenon was most generously present, not only on the abdomen and chest, but over the entire body surface. The diagnosis was almost purely clinical. There was little apparent need for microscopic confirmation of our fears. Indeed, I am now quite in sympathy with an elderly physician of my acquaintance who once unburdened himself to me in the following terms: "When you have a patient between the age of 10 and 50, especially if it be in the fall of the year, who has complained of general depression for a week, and then becomes bedridden with a temperature higher each day, the sooner you decide the case is one of typhoid the sooner you are right." Gilman Thompson voices the same sentiment when he says: "It is a good rule to suspect typhoid fever as present, with any temperature not explained by demonstrable cause, which lasts for three or four days without complete morning intermission especially if the facies be dull and dusky, and the tip of the tongue be sharp and red, with prominent papillae."

It is not my wish to ignore the serum diagnosis, nor to belittle the claim of blood counts, but the average physician is not supplied with a pure culture of typhoid bacilli, or even in touch with a laboratory which is thus prepared to make the Widal test. The Widal reaction was obtained very positively in the six cases in which it was made in this epidemic. About the time we were able to get our cases into the improvised hospital the question of diagnosis was raised again by certain conventional people, and so we called Dr. L. W. Littig, of the chair of medicine at the State University. He confirmed the diagnosis, assisted very materially in the organization of the hospital and gave us many valuable suggestions.

*Classification of Cases.*—The clinical picture of typhoid fever is so varied that one speaks of typical or atypical cases with a considerable lack of definiteness. To be properly considered atypical a case must present a very unusual symptom complex in typhoid. From a purely clinical standpoint the division into the abortive, the ambulatory and the grave forms is convenient. In this epidemic we had typhoid with intestinal lesions in every one of the 42 cases. There were 5, and possibly a 6th, in whom the intestinal involvement was slight, but general infection was markedly present. It is somewhat remarkable that in a list of 42 there should have been none of the rather common pneumo-typhoid. We had one case which was properly a spleno-typhoid. It is true that there was one case which suffered from an intercurrent attack of pneumonia, and another who had acute mania, but these must be considered complicated cases rather than varieties. From the clinical basis there were of the abortive typhoid 4, of the mild variety 7, of grave form 18, and of very severe or intensely grave nature 13. Those considered very grave were cases in which there existed serious complications accompanied by profound infection and prolonged duration of the disease. Those considered grave suffered from exaggeration of all the phenomena common to typical typhoid, and many of them had complications of varying severity. That group of cases chronicled as mild were typical cases not accompanied by severe complications, but which continued for from four to six weeks uneventfully through the successive stages of the disease.

*Complications and Special Symptoms. Intestinal Hemorrhage.*—Intestinal hemorrhage occurred in 7 of the 42 cases, or 16.66 per cent. Most of the hemorrhages

occurred in the latter part of the second week or later, but there was one case in which from one to eight ounces escaped from the bowel from one to six times in each twenty-four hours, beginning in the first week and ceasing two weeks later. He made a good recovery after sixty days of illness. Another case was peculiar in that every time he had an enema, be it ever so small a quantity and ever so soothing in quality, the procedure was followed by hemorrhage. There were bloody evacuations at other times, but this peculiarity was interesting. In those cases where the actual loss of blood was considerable the prompt use of normal salt solution seemed to strengthen the patient rapidly, but one of our deaths was due to very large hemorrhages frequently repeated.

*Cardiac Complications.*—One young man who had been an habitual user of large amounts of tobacco had a weak heart to begin with. We feared very much for this patient, but under generous allowances of strychnia and digitalin with most persistent bathing, he weathered the storm nicely. There was only one pronounced case of endocarditis, one of pericarditis (following an intercurrent pneumonia) and six cases of myocarditis or cardiac myasthenia. All the cardiac cases recovered.

*Respiratory Complication.*—There was but one real complication of this sort, though about half the cases showed some slight bronchial irritation early in the disease. One patient contracted a left-sided lobar pneumonia in the second week of his illness. He passed through the stages of pneumonia in a manner seemingly independent of the typhoid. After resolution he continued the usual indications of uneventful typhoid, but in a few days developed pericarditis, with slight effusion, and finally, after numerous pseudo-collapses and the lapse of eighty-three days, recovered without sequela.

*Phlebitis.*—Occurred in five patients—both limbs being affected in one of the cases. These cases were prolonged as result of the thrombosis and suffered quite as much as did those who had neuritis, but all made good recovery. It developed invariably late, not earlier than the fifth week.

*Neuritis.*—This was experienced by four cases. In each instance the nerves of the feet and toes were affected. The slightest touch was painful, and no voluntary movement could be made by the patient without the penalty of most intense pain. Like phlebitis, neuritis occurred very late in the disease, and recovery was finally complete in every case.

*Hyperpyrexia.*—There were three patients whose temperature reached a point higher than 106 F., one of whom sustained for three hours a registration of 107.2 and recovered. This temperature was at the outset of endocarditis and was followed by profound collapse which nearly cost the patient his life.

*Intestinal Perforation.*—This occurred in one case and remarkably early, being on the eighth day of the fever. It was sudden, without ascertainable cause, and death followed within twelve hours, due ultimately to collapse. Surgical interference was impossible owing to the profound shock.

*Acute Mania.*—A lady student, aged 30 years, developed acute mania with suicidal tendencies at the very onset of the fever and continued through an otherwise mild attack of the disease. Her mind gradually returned to a more nearly normal state, but had not entirely cleared when she passed from our observation two weeks after the temperature reached normal. She was an exceptionally fine student and especially interested in psychology. No doubt her excessive brain work had much to do with her mentality during the attack.

#### TREATMENT.

There was no specific treatment unless, indeed, the routine administration of baths and other stimulants may be considered specific treatment.

*Baths.*—To most patients cold baths were given whenever the temperature reached 102.6. Those whose temperatures did not reach that during twenty-four hours were given tepid sponging at least once each day. Cold sponging was substituted for cold emersion bath in a few instances where the sponging was found sufficient to reduce the temperature satisfactorily. The actual all-over baths were given with water but slightly warmer than ice. Ice was kept constantly in the water and packed about the head. These baths were continued from five minutes to as long as a half-hour in extremely high temperature of persistent character. Large rubber sheets were used by being placed under the patient as is any sheet, then by pinning the head and foot to the bedstead and rolling up the sides a veritable bath tub was made which would hold, besides the patient, four or five pails of water. If he were able the patient was encouraged to rub himself while from two to four people were kept actively at work on the skin. In those whose temperature had shown tendency to persist in spite of previous baths and in cases not accompanied by severe intestinal hemorrhage, several pints of iced water were thrown into the colon by means of a 15-inch rectal tube, during the bath or immediately following it. In many instances the patient would complain bitterly of the bath, the teeth chatter, the skin become cyanotic, etc. But generally in a short time the buccal temperature would be somewhat lowered, pulse become stronger and less frequent, delirium lessened, subsultus cease, earphlogia disappear, and by the time the patient was out and wrapped in dry woolen blankets, many times, would be asleep perhaps for the first time in twenty-four hours. I have known patients to waken after two or three hours of this "post-hydral" sleep mentally clear and physically improved beyond the most sanguine expectations. Weak heart instead of being a contra-indication positively indicates such treatment in high temperature. Menstruation is no contra-indication, nor is intestinal hemorrhage, nor again profuse epistaxis or apparent nervous collapse, provided in the latter instance the temperature is as high as 103. It is said that phlebitis and neuritis are more frequent complications under this treatment than by other methods. But between a living patient with one or both of these complications and a deceased one with neither, one very much prefers the former. I can not understand how any man who has watched a series of cases under this treatment, properly supported by such medicinal measures as are indicated from time to time, can possibly question its superiority over any other method.

Probably the practice next nearest the routine in this epidemic was the administration of strychnia. Whenever the first sound of the heart began to be weak, whether it was in the first week or later, the strychnia was exhibited, sometimes by mouth, but when the myocarditis became marked it was given hypodermically—in some cases so often and heroically as 1/20 grain every three hours. In many cases brandy or whisky was added and sometimes substituted for the strychnia. There were, however, cases in which from a cardiac standpoint neither strychnia, alcohol or the combination of the two, seemed to accomplish good circulation. Here digitalis was administered—generally in the form of hypodermic injections of digitalin. When given in or-

dinary doses no results followed, but at the suggestion of Dr. J. T. Priestley, of Des Moines, who saw the cases with us at one time, we employed digitalin in hypodermic doses of  $1/18$  to  $1/8$  grain and obtained finally the characteristic effect of digitalis in spite of high temperature. However, digitalis seemed totally without the sustaining power which is obtained by strychnia in conjunction with cold baths.

In the matter of medicines perhaps the next most used drug was calomel in combination with sodium bicarbonate. In the early stages—first and second weeks—this combination was prescribed for all patients whose bowels were not moved at least once a day. A tablet containing calomel  $1/5$  grain and sodium bicarbonate  $1/2$  grain was given every half, or in some instances every hour, until the bowels were evacuated or until ten were taken. Frequently this was followed by from one to three ounces of honyadi water, or a small dose of magnesium sulphate, but not in every instance did we deem the saline essential. We did not hesitate to exhibit the calomel later in the disease, and saw only most happy results. The only contra-indication was intestinal hemorrhage. I am aware that so eminent an authority as J. C. Wilson recommends the use of small enemata daily to accomplish the required movement, but I learned to dread the use of the enema after witnessing the occurrence of copious bright red hemorrhages in three cases immediately following its use, and a repetition of the hemorrhage in one markedly tympanitic patient at each succeeding attempt with the enema. I believe the secret in the management of constipation throughout the disease is in persistently procuring a daily movement. Compound licorice powder, cascara cordial and a pill of podophyllin, belladonna and physostigma were employed with success, but nothing seemed more satisfactory than calomel as used above.

In diarrhea beta-naphthol bismuth acted kindly, as did rather large infrequent doses of guaiacol carbonate. When tympanites was marked the old-time turpentine emulsion made without egg proved quite satisfactory, though there were instances in which six grains of guaiacol carbonate every four hours was really more efficacious.

Of the 42 cases treated at the college 2 died, a percentage of mortality of 4.7. Of the 23 who were treated at their homes, 3 died, a mortality of 13 per cent. This is a great argument in favor of hospital treatment of typhoid.

## THE IDENTIFICATION OF CRIMINALS THROUGH THE FUNDUS OF THE EYE.

M. F. WEYMANN, M.D.

Professor of Ophthalmology and Otolaryngology, Central Medical College,  
ST. JOSEPH, MO.

Commensurate with the importance of the certain identification of criminals have been the efforts at elaborating a reliable system for this purpose. Most prominent in this line stands out the method of M. Bertillon: yet even in it there occur so many data subject to change by reason of growth, voluntary effacement or disfigurement, that further additions are by no means undesirable.

I wish here to call attention to the fact that anybody could at any time, with a certainty, be identified by the anatomical conformation of the fundus oculi; in fact, the disposition of the arteria centralis retinae and its branches alone would be sufficient for the purpose.

I admit that a casual observation would fail to do so, but identification by a previously made—and that with the greatest exactitude—drawing of the fundus would leave no room for doubt. While there are many details sufficiently characteristic in the papilla, yet there is enough inconstancy to make them unavailable. This is not true of the vascular branching on the papilla and in the peripapillary region. Text-books describe fully the retinal vessels, usually according to Leber's description, which is a good one, indeed, but, after all, it is only schematic. For reference, this is quite sufficient, but, in this manner, there has been produced in the minds of oculists the idea that the anatomical arrangement is fairly constant—a belief thoroughly erroneous.

I could extend this article *ad infinitum*, as I am in possession of several hundred fundus records which plainly prove my statements. However, any fairly proficient ophthalmoscopist can so easily prove my assertions, that I prefer confirmation by others. If at any time detailed data should be desired, I should be most willing to submit them. My proposition reads thus:

Absolute identification can be obtained by a drawing (exact as a photographic reproduction or nearly so) of the papilla and a surrounding retinal circle distant from the scleral ring by two papillary diameters. So great is the multiplicity of the anatomical relations of the vascular twigs that I have never been able to find even two fellow organs exactly alike.

The points to be considered are:

1. The method of division (dichotomous or otherwise).
2. The exact point of division.
3. The exact angle of the vessels with the primary meridians.
4. The exact distance of one divisional point from the other.
5. The relative size of the divided twigs.
6. The angle of division.
7. The course of the twigs (straight, curved, etc.).
8. The exact distance, everywhere and at every point, between venous and arterial branches (parallelism, convergence or divergence, twining, etc.).

While other marks may be added, they are, though perhaps valuable, not needed. No knowledge of pathology is required. Identifying inspection could not be made by a collective glance, but only by the most scrupulous attention to every structural detail. It would, therefore, require some time. The only condition able to impair the value of this test would be impossibility of fundus exploration due to clouding of the media.

Inordinate enthusiasm and positivism very often bear the earmarks of immature consideration, but, in this instance, I beg my confrères to ignore this circumstance by lending their help to verify the truth of assertions fraught with so much practical importance.

**Radiotherapy of Lupus.**—Leredde reported at a recent meeting of the Paris Société de Thérapie that he had treated during the last year 43 patients with lupus of one to thirty-five years' duration. They had a previous record of 1796 thermo- or galvano-cauterizations, 908 séances of scarifications, 7 deep cauterizations under chloroform, 61 applications of high frequency electricity and 295 injections of tuberculin. Only one patient had been cured by these measures and the lupus had recurred later in him. None of the rest had had even a small segment of the lupus cured. Under radiotherapy 8 are now completely cured; 7 seem to be cured, but the interval is not long enough for certainty.

## The Organization of the Medical Profession.

(Continued from page 461.)

### VII.

#### UNIFORMITY OF ORGANIZATION OF STATE SOCIETIES NECESSARY.

The organization of most of the state and territorial societies was adopted without any idea of conforming to a definite plan. The constitution or organic law of each was made in accordance with the views of the little band who gathered to form the new society, and no central or national body attempted to guide them so that they might follow any particular system. In fact, thirteen of these state societies were in existence before the American Medical Association was started, and five more were formed before it could have outlined any system for them to follow had it attempted to do so. We find, therefore, what might have been expected, that no two are organized on the same plan in every particular. Some are incorporated and recognized by the law of the state, and are endowed with certain legally defined functions, such as the power to hold property; others have still further powers granted them, as the right to appoint officers of certain boards, of granting license to practice, etc., and some are incorporated with practically no powers. The great majority, however, are not incorporated, and consequently have no existence in the eyes of the law. But whether they are incorporated or not is immaterial as regards their relations to the American Medical Association, yet there are many reasons why state societies should be legally recognized; in fact, this will be necessary if some of the work contemplated should be taken up.

Aside from this difference in the organic laws, there are other differences that are extremely important, and these must be eliminated if the plan of bringing the state societies together, as proposed, be carried out. We refer to the relation they bear to the subordinate societies in the state. In this regard the various state organizations may be divided into three classes: 1, those in which the county or district societies are federated in the state society, membership in the subordinate body carrying membership in the state; 2, those in which there is an only indirect relationship between the two, and 3, those that do not recognize in any manner any subordinate society. In the first class are Alabama, Connecticut, Indiana, Massachusetts, New Jersey, New York State Medical Association, and Pennsylvania, although no two of these are organized at all alike, aside from the fact that membership in the lower carries with it membership in the higher body. As regards the second class, the relationship between the state and the county or district societies varies greatly in different states; but it would take too much space to show here in what this difference consists. Some that theoretically are classed in this second division really belong to the third, namely, those which ignore the existence of any other societies whatever, and do nothing to encourage or foster them. In this third class belong the larger number of the state societies.

To change this unsatisfactory condition is the first and most important work to be done in the organization of the profession of our country. Touching on this we quote from the report of the Committee on Reorganization:

"No successful organization of the profession is possible without the mutual coöperation of the state so-

cieties. There is at present no close relationship among the state societies; each is an independent body recognizing no other, and no concert of action among them regarding measures of mutual importance is possible under present circumstances. It will be accepted as an axiom that before such a federation can become an established fact a common plan of organization must be adopted by all. To successfully accomplish this and have such a common plan accepted by each state society, it will be necessary that each of these bodies shall be willing to sacrifice for the common good certain minor details in their present plan of organization, certain preconceived ideas as to what are the objects of the state medical society, and existing methods of procedure of minor importance. For without a willingness on the part of all to make some minor sacrifices, there can be no successful issue to the undertaking, and present chaotic conditions with their resulting weakness will continue to prevail."

In this part of the report the Committee was making a plea: 1, to get the American Medical Association to reorganize so that it might be a body in which the state societies could affiliate, and 2, to have the state societies reorganize on a more or less uniform basis, so that a federation might be possible. The recommendations as regards the American Medical Association were adopted by that body. The state societies are asked to adopt that part of the recommendations which refer to them.

There must be a uniformity of organization as regards certain fundamental principles before a true representative federation is possible. It will be impossible to get a truly representative national body made up of delegates from the state societies in the way the latter are at present organized. Delegates to the House of Delegates of the American Medical Association from a state society in Classes 2 or 3, as defined above, would not be representing the profession of the state, because the body that sent them would not represent the state, but only one independent society in the state.

#### Division of the State Society into Two Branches.

While it is immaterial whether or not the state societies organize alike in every particular, it is important that they conform as regards certain fundamental propositions. These are specified in the recommendations made by the American Medical Association, and are, 1, separating the annual session into two branches, legislative and scientific; and 2, making membership in the county or district society carry with it membership in the state society. As regards the first proposition, the wording of the recommendation to the state societies is "to divide their annual meeting into two branches, legislative and scientific; the legislative branch to be as small as is compatible with representation from all the county societies, and to be composed of delegates elected by the county societies."

While seven state societies already have two distinct branches, in none of the others does this division exist. In the annual gathering of these there is no distinct business body, nor, for that matter, a distinct scientific body. On the contrary, the annual meeting is simply a general one for any and all purposes, and is made up of those who come without any delegated authority. The meetings are not representative, but are liable to be dominated by those living near the place of meeting, or by those coming from a large city, if there is one in the state. Such meetings may be, and often are, controlled by those who want a certain set of officers elected, or by those who want some pet measure carried or endorsed. Much feeling and almost a disruption of a

certain state society occurred a few years ago because a large number went from a certain town, packed the meeting, and elected their favorite as President. Such occurrences would be impossible if there were a small legislative body to transact the business of the association, made up of delegates elected by the county or district societies.

While the annual meetings are unrepresentative, they are, as a rule, too large to be able to deliberatively consider important questions. This is especially true in the larger states. Further, those who attend the meetings do so for scientific and social purposes; very few have the inclination to take part in, or will give time to medico-political discussions, or to the consideration of business or legislative problems. If such matters are brought before the meeting, there is always developed an impatience on account of time wasted, and thus important topics are not deliberatively considered but are acted on with undue haste; or, what is more common, they are not acted on at all but laid on the table or indefinitely postponed.

We are only repeating what everyone knows who has attended the average state society meeting. It is exactly the same condition, only in less degree, that has prevailed for years in the annual meetings of the American Medical Association, but which has been remedied by the creation of the House of Delegates.

Aside from the fact that in such meetings the necessary consideration of important business and medico-political matters are interfered with, the scientific and educational work is also greatly hindered. There is always some legislative work brought before the meetings; if nothing more there are usually some vexatious ethical troubles, besides business pertaining solely to the society itself, and the election of officers—the latter often no small consumer of time. The great majority of those present have only an indifferent interest in these matters; they have attended the session for scientific work and it is not just to ask all of them to waste their time in an interminable debate on matters in which they are not interested. In brief, the general meetings are unsatisfactory either as business bodies or as scientific gatherings; hence, neither one nor the other of these functions is properly exercised.

#### **The Business Body.**

It will no doubt be appreciated that when the American Medical Association recommends the division of the state society into two branches, it is really asking that there be created a small representative body which shall have full control of all business and legislative matters, the scientific work of the general annual meeting going on as now, although, it is hoped, improved in certain particulars. The business body should be as small as is consistent with fair representation, and while in some respects there may be much wisdom in a multitude of councilors, the disadvantages of an unwieldy body greatly exceeds the advantage of the little extra wisdom that may be obtained by large numbers. The smaller in reason a deliberate body is, the more effective it is for work. If possible, the membership of the legislative body of the State Society should not exceed 50 or 75. The difficulty to be met, however, is that there are more counties in the majority of states than this number and it is absolutely necessary that every county society have a representative. But it often happens that in many states a county in which there is a large city is liable to dominate the State Society. In these cases there is usually a jealousy or rivalry between the country and

city. The little county society, the one to be most encouraged, is liable to feel that its influence is dwarfed by that of the larger. For these reasons and for the purpose of making the legislative body small, it would be well if in many states the apportionment of delegates might be made large, say one delegate to every 100 members or fraction of that number. In this case the small county society would have an abnormally large proportionate influence, but there would be no harm in this. If this ratio were adopted in Illinois, for instance, the Chicago Medical (Cook County) Society would be entitled to but 10 delegates and as there is no other county society in the State with a membership exceeding 100 and as there are 102 counties in the State, the business body of the Illinois Medical Society would consist of 111 members if every county were represented. The Chicago Medical Society might object, but as it will probably be found that in those counties in which there is a live active society there will be at least three-fourths of the regular profession of that county on its membership rolls, and as not one-third of the regular profession of Cook County belong to the Chicago Medical Society it might stimulate this body to do a little more active work in organizing the profession in its territory than it is now doing. At present it would have as much influence as 10 county societies. If it were built up as it should be and had three-fourths of the regular profession on its rolls it would have a representation equal to 25 or 30 counties, even with this high apportionment.

In Pennsylvania, which in a certain way has the county society plan and the business body separate from the scientific nominally, there would be under this apportionment three counties entitled to more than one delegate, namely, the Philadelphia County, 8; Allegheny County, 4; and Lancaster County, 2. As there are 67 counties in the State the business body would be composed of 78 members, which would be sufficiently large to be representative.

It may be asked why it is necessary to create these business bodies now, why the methods of the past should not be allowed to continue. In reply it may be said: 1. In the past the majority of the state societies have been, to all intents and purposes, purely scientific bodies and, as such, they had no need of the proposed business branch. In the future it is expected that each state society will widen its scope of action, coöperate with other state societies, and assume all the functions which a body representing the profession of a state should assume. 2. While most of the state societies, in annual session, are now too large to calmly deliberate on the important questions that should and do come before it, yet in the future, if the recommendations of the American Medical Association are adopted their membership and the number in attendance at the annual meetings will greatly increase. 3. A body assuming to pass judgment on matters affecting the profession of the whole state, and maintaining for itself the right to appear before a legislature in behalf of all the physicians of the commonwealth, or in any way claiming to be representative, should be composed only of men duly delegated to speak for those they assume to represent, and the method of their appointment should be such that even the most obscure reputable practitioner can have his part in their selection.

1. At the annual meeting of the Philadelphia County Medical Society, January 15 last, it elected 150 delegates to the Society of the State of Pennsylvania. The number from this county society of itself would make a body too large for deliberative work. What then must be the business body if every society in Pennsylvania should send its full quota?

## EXPERIMENTAL INVESTIGATIONS RELATING TO SURGICAL OPERATIONS.

Surgical anatomy, normal and pathological, has received and is receiving much attention. It occupies a conspicuous place in literature, almost overshadowing wholly what Crile calls surgical physiology, the importance of which from a surgical standpoint does not seem to be appreciated as much as desired. Yet it is very clear, even self-evident, that many surgical operations require ready and exact application of definite knowledge of human functions, gained to a large extent by animal experimentation. It is with this idea that George W. Crile of Cleveland has been carrying out a number of experimental researches bearing upon problems connected with surgical operations. A good example of the sort of work he is doing is furnished by the interesting essay from his pen printed elsewhere in this issue. Studies in the laboratory of various phenomena produced experimentally are made to yield conclusions of direct practical value in the operating room. The larger essay in which Crile records the results of his more extended work in this field was awarded the Alvarenga prize for 1901 of the College of Physicians of Philadelphia.<sup>1</sup> It may be of interest to briefly note the more important phases of Crile's work. The effects of dividing or mechanically irritating the vagus nerves naturally come up for consideration in various operations on the neck. It seems that the statements in the literature upon these points vary considerably. In his experiments on dogs Crile finds that mechanical irritation of the vagus nerve causes more or less slowing of the respiration and in most instances a rise in blood pressure. Sometimes an inhibitory effect was noted, but in no case was there complete inhibition of the heart, even when the vagi were mechanically destroyed. Division of one vagus has but little effect upon either respiration or circulation. Severance of both vagi causes rise of the blood pressure and increased frequency of the heart's action; while the respirations are lessened in number, the amplitude of the excursions is so much increased as to practically counterbalance the slowing. "The respiratory mechanism was much more affected than the circulatory, and exhibited early signs of exhaustion." Several clinical cases are cited in which a close correspondence was noted between the effects of necessary operative lesions of the human vagi and those mentioned in

the foregoing, from which fact it is probably permissible to infer that the surgeon need not be deterred by fear of the disastrous effects of vagal irritation and division from executing various mutilating maneuvers necessary for hemostasis, complete removal of malignant tumors, etc.

A large series of experiments on dogs were made in order to study the effects of intravenous infusion of saline solution, and the results are discussed fully under various headings. The most important conclusions are that when blood pressure is lowered by a not too excessive hemorrhage, saline infusion promptly restores the lost pressure, but that when the vasomotor mechanism is destroyed infusion has no effect. If the peripheral resistance is lost from "shock" no amount of infusion is able to restore the lost pressure—infusion is without avail then because one of the necessary factors to establish blood pressure is removed. Between the two extremes here given, infusion is effective in proportion to the impairment of the vasomotor innervation. Crile's experiments and discussion of these weighty questions will interest greatly surgeons and others; the question is too broad for further notice at this time.

The physiologic action of cocain and eucain when injected into the tissues is considered also.<sup>2</sup> Among other interesting observations it is especially noteworthy that the injection of these substances into a nerve-trunk promptly "blocks" both afferent and efferent impulses. General anesthesia does not prevent the passage of afferent stimuli that may produce shock. Cocain or eucain applied upon the medulla or fourth ventricle suspends action of the respiratory center. The "blocking" action of cocain and eucain makes it possible to operate upon the extremities without pain and shock by injecting a one per cent. solution into the supplying nerve trunks—a method of signal value where general anesthesia is contra-indicated. Crile cites a number of interesting illustrative cases; perhaps the most striking are two amputations of the shoulder. Inhibitory reflex arrest of respiration and heart's action may follow manipulations of the pharynx and larynx; cocain or eucain applied to the mucous membrane wholly prevents such reflex inhibition ("laryngeal collapse"). From the fact that shock may be avoided because afferent impulses are blocked by cocain or eucain it may be permissible to suggest the use of these substances by intraneural or sub-arachnoid injection as preventives of "shock" in cases of crushing and other injuries that come under observation immediately after the accident.

In the last section of his essay Crile deals with the effect of temporary closure of the carotid arteries. The literature is reviewed and then the experimental and clinical observations are presented. In order to control hemorrhage in various operations upon the head and neck Crile recommends a preliminary injection of atropin (1/100 grain) in order to prevent possible inhibition

1. Problems Relating to Surgical Operations, Philadelphia, 1901.

2. See first article in this issue.

of the heart from involvement of the vagi; the temporary clamping of both common carotid arteries by means of a special device; to prevent entrance of the blood into the lungs the patient should be placed in the Trendelenburg posture; and in operations involving the pharynx or larynx the application of cocain to the mucous membrane. In this way operations of the head and neck may be rendered so much safer "as to greatly increase surgical possibilities."

The industry, ingenuity and judgment manifested in Crile's experimental study of surgical physiology and in the clinical application of the results seem to make the work outlined of much practical value and interest to surgeons. The researches illustrate well the great value of the experimental method in this special field.

#### ORGANO-THERAPY IN UREMIA.

Since the work of Bouchard showed so clearly the toxicity of the substances normally eliminated by the kidneys, and retained under conditions of renal insufficiency, other possible agencies in the production of the condition resulting from such renal insufficiency have been overshadowed and lost from view. Recent studies of the functions of the kidney that are other than eliminative lead to a reconsideration of the subject, and suggest that perhaps after all the retention of normal metabolic products is not the only factor, possibly not the chief one. That the kidney produces an internal secretion that is of further use within the body is scarcely to be doubted, *a priori*. Probably among the products of cell activity in every tissue are some substances that are available, if not essential for other tissue cells. In the kidney, however, the excretory function is so prominent that its other possible functions have escaped general observation, both in experimental and clinical studies.

The experiments which have demonstrated the importance of the "internal secretion" of the kidney are of two chief types. First, those in which the renal tissue is reduced to a minimum by operative procedures. Bradford<sup>1</sup> found that removal of two-thirds of the entire kidney substance in dogs did not cause death, but if three-fourths were removed death followed in one to six weeks through asthenia, but not from uremia as ordinarily manifested. When so little as one-half of one kidney remained the elimination of urine was normal both as to quantity and solids. In spite of the normal urea elimination in such cases a marked increase in nitrogenous extractives occurs in the tissues, especially in the muscles. As the amount of these substances is much greater than that resulting from simple urinary retention, and as there is much wasting of the tissues, Bradford suggests that on account of the absence of the internal secretion of the kidney there results a breaking down of the muscles and to a less extent of the other structures of the body.

Vitzou<sup>2</sup> has worked with the other method, which

studies more directly the effect of the hypothetical internal secretion. He followed up the experiments of Brown-Sequard and d'Arsonval, who had showed that dilute extracts of renal substance prolonged the life of animals made uremic by double nephrectomy, and of Meyer, who found that the Cheyne-Stokes respiration of dogs under similar conditions was arrested by injections of renal juice, normal blood, or blood from the renal vein. Vitzou found that blood from the renal vein had striking effects on uremic animals. The symptoms were promptly stopped, and for a time the animal would appear quite normal. Repeating the injections whenever uremic symptoms returned prolonged the life of animals deprived of both kidneys, and which usually died in twenty-four to forty-six hours, to over one hundred hours, in one case to one hundred and sixty-four hours.

From these experiments it seems that the kidney turns into the blood some substance which seems to act as an antitoxin to some other unknown substance, which in turn is either toxic itself or acts, as Bradford thinks, by causing tissue waste. Organo-therapy in renal disease suggests itself at once as the natural outcome. It is significant that the form of nephritis associated with most marked uremic manifestations is the one in which there is the greatest loss of renal tissue, the chronic interstitial nephritis, and so the theoretical results obtain confirmation. A few trials of defibrinated blood from the renal vein of goats have been made in nephritics, and it is stated that amelioration of the symptoms followed. As yet such treatment is not generally practicable, and much more experimental data must be obtained, but the hope of aiding the otherwise hopeless nephritic should be sufficient incentive to much work along these lines.

#### SKIN ERUPTIONS AND VISCERAL LESIONS.

One of the most interesting practical advances in our knowledge of disease in recent years has come from the gradual development of the doctrine that internal viscera are often affected by the same virus that causes cutaneous eruptions. Until within the last ten years it was the custom to consider skin diseases under ordinary circumstances independent of internal organic affections. The discovery that certain skin lesions such as peliosis and purpura were evidently of rheumatic origin and that even such ordinary skin diseases as roseola, urticaria, erythema and certain forms of herpes were so frequently associated with rheumatism as to be surely connected with it etiologically was the first definite advance in knowledge that pointed out the intimate relation of the skin to affections of organs deeper seated.

More recently Osler described various visceral complications that occur with erythema multiforme. At Heubner's clinic in Berlin it was noted that an intra-abdominal rub, probably due to the friction of slightly affected peritoneal surfaces of intestines upon each other, could be often felt in so seemingly superficial a skin affection as measles. Koplik's description of intra-oral spots in

1. Journal of Physiology, 1899, xxv, p. 18.

2. Jour. de Phys. et de Path. gén., 1901, III, 901 and 926.

this same disease probably points to the fact of a rather general involvement of the mucous membranes of the gastro-intestinal tract in the affection. In a word, it has become ever clearer and clearer that the skin seldom suffers alone in any disease and that lesions at least analogous to those on the skin occur in various internal organs during the course of cutaneous eruptions.

It is not surprising, then, that Van Harlingen<sup>1</sup> in a review of the recent literature as to the nature of herpes zoster admits that in a certain number of cases various visceral complications may accompany this form of herpes. These internal complications consist, so far as our present knowledge goes, mainly of paralyses of sensory or motor nerves, inflammations of the pleura and peritoneum, articular involvements, and occasionally visceral ailments analogous to the skin lesions. The later advances in our knowledge of herpes zoster, especially its frequently reported occurrence in groups in recent years so that it assumes something of the character of an epidemic, has prepared medical men for the acceptance of the doctrine that herpes zoster is a specific fever. It has, of course, the prodromal period of malaise, temperature and discomfort; then a characteristic eruption with remission of the symptoms and a definite course to run before cure is complete. Van Harlingen calls attention to Head's statistics of the recurrence of the disease, only four times in 400 patients, as probably indicating that one attack of zoster provides a modicum of protection against subsequent attacks. Admitting, then, that herpes zoster is a specific fever, it is to be expected that viscera would also be affected by the virus of the disease and another link in the chain connecting cutaneous affections with visceral lesions is complete.

Dr. Roland Curtin<sup>2</sup> has just presented a series of cases that seem to demonstrate the occurrence of visceral lesions in patients suffering from typical herpes zoster. In nearly one-half of his cases the internal pathologic condition preceded the cutaneous appearance of the zoster. In most of the others the developments, internal and external, seemed almost simultaneous. The joint involvement in one of his cases is especially interesting because it carries with it some confirmation of the theory that arthritic inflammatory conditions are usually not diathetic but specific in nature and origin. The trend of modern medical thought is evidently towards the acknowledgment of specific viruses as the most frequent cause of disease and the effects of each virus is not as distinctly localized as has been thought. Typhoid fever is not merely in the intestines, nor measles in the skin and external mucous membranes, nor rheumatism limited to serous membranes, any more than so-called skin diseases are confined to the cutaneous tissues. In all disorders specific affections of parts distant from the original localization may be looked for and they serve to explain many hitherto obscure symptoms.

#### EARLY DIAGNOSIS OF CERVICAL CANCER.

Much recent literature on cancer of the cervix, both European and American, has been a plea for earlier diagnosis in this common and deadly form of uterine disease. Under present conditions patients so often present themselves too late for operative relief that some hospital records show nearly as many cases turned away as are received. Even when operation affords some hope it is generally performed so late that the necessary extensive removal of tissue gives a very high primary mortality and in the immediately convalescent cases renders great the chance of recurrence. The figures presented by even the more hopeful writers are disheartening—the freedom from recurrence is calculated as not higher than 10 per cent. There is now little to expect in the way of improved technic, so, barring any discovery of a non-surgical cure, the only hope is in the earliest possible diagnosis.

Early diagnosis of cervical carcinoma rests clinically upon the investigation of even slight hemorrhages. The other classical symptoms of pain and odorous discharge mean, respectively, that the cancer has spread beyond the actual cervical tissue and that the diseased tissue has become secondarily infected. Gynecologists insist that the general practitioner has practically the only professional opportunity for early suspecting the diagnosis. He must suspect and immediately investigate every case where there is irregular bleeding before or after the menopause, occurring with or without irritation, such as coitus or douching. The early suspicion of a case is the prime necessity—investigation can then be carried out by clinical or laboratory examinations. However, the matter by no means rests entirely in the physician's hands, because he can not compel a woman to consult him about slight "bloody shows," more especially if the hemorrhages occur near the climacteric, which is popularly supposed to account for any irregular bleeding during a considerable period of years.

The duty of the family physician lies in educating women whose confidence he possesses, so that they may be insured as much as possible against the unrecognized inroads of cervical cancer. He should tactfully attempt the teaching of common-sense watchfulness with avoidance of hysterical worrying about the matter. To this end he must be willing to confidently assume the responsibility of declaring whether or not there is cause for alarm.

#### AN OBJECT LESSON IN ANTI-VACCINATION.

A Boston anti-vaccinationist crank recently exposed himself by deliberately visiting the isolation hospital and is now suffering from the effects of a severe attack of smallpox. Another, one of the two physicians in the city of Camden, N. J., who opposed vaccination, died the other day of the same disease. The Wisconsin anti-vaccination fanatic who deliberately exposed himself and others appears to have so far escaped, but the town where he lives is suffering from an epidemic which may

1. Amer. Jour. Med. Sciences, January, 1902.

2. Amer. Jour. Med. Sciences, February, 1902.

be largely due to his agency in disseminating the pest. It is a pity that he is apparently immune—perhaps by vaccination in infancy—not that one wishes to see him suffer; but because his escape is advertised by him as proof of his theories, and as a result the health officials are embarrassed or even hindered in their work in combating the epidemic. If his exposure had meant only danger to himself the case would be different, but his carrying the infection to others and his example and teaching are under the circumstances nothing less than criminal. It is said that in London where the present pandemic of smallpox is raging, there is, in view of the approaching coronation festivities, a panic among those who expected to share the profits from the crowds attracted by the occasion and that insurance companies are charging high rates for insurance against smallpox. The anti-vaccination propaganda has had its way so much in England that a very considerable proportion of the people are unprotected. In this country it has perhaps been less effective, but present conditions indicate that we are none too well off in this respect. If a few more of the blatant anti-vaccinationists would only furnish an object lesson like the eastern physicians mentioned it could perhaps be said that they did not suffer or die in vain.

#### IODOPHILIA.

Iodophilia is the reaction which certain leucocytes give when a dry blood-film is brought in contact with a solution of iodine and potassic iodide in mucilage of gum arabic. Normal leucocytes are colored bright yellow, but in certain pathological conditions, such as septicemia and uremia, the polymorphonuclears contain reddish-brown granules, or show a diffuse brownish coloration. Similarly colored larger and smaller masses may occur outside the corpuscles. The number and the grouping of the intracellular granules and masses may vary. They are mostly irregular in form. In their recent study of iodophilia Locke and Cabot<sup>1</sup> point out that Ehrlich first called the attention to the occurrence of iodophilia, especially in pus. Since then its occurrence in blood has been studied by Galritschefsky, Czerny, Lieviero, Goldberger and Weiss, and others. From their observations on over 400 cases Locke and Cabot conclude that extracellular brown masses are found in normal as well as pathologic blood, and that only large numbers are to be regarded as of pathologic significance. They are increased in diabetes and sometimes in chronic suppurations. But the intracellular masses are probably always pathologic, although they are not characteristic of any special disease or condition, being, however, most constant in sepsis and purulent infections. The authors claim that iodophilia is a certain sign that the patient is ill. It occurs also in bacterial toxemias, in uremia, in respiratory disturbances, and in grave anemias. Much work remains to be done before the exact significance and the actual diagnostic value of the test can be fully determined. The method of examination for iodophilia is very simple and the staining with the iodine solution does not at all prevent a more general examination of the blood at the same time. It does not seem that the nature

of the substance or substances giving the reaction has been determined. Glycogen gives a similar reaction with iodine, and so does amyloid material. At the present time iodophilia may be classed with phenomena like leucocytosis, fever, and the diazo-reaction, as a sign of the presence of morbid processes within the body, and as such it would seem to merit careful investigation in routine examinations of the blood.

#### IOWA MEDICAL LAW AND OSTEOPATHY.

An Iowa judge has issued a mandamus writ compelling the State Board of Medical Examiners to grant certificates to graduates of an osteopathic school. The grounds for this action, as given, are apparently that osteopathy is excepted by the statute from the laws regulating the practice of medicine, that the Board of Examiners have no right to establish any minimum standard for schools of osteopathy, and that the standing of a school in good repute could not be estimated by the Board from its actual character, but only from the opinion of osteopaths and others in regard to it. It is a little puzzling to see why the statute should give the Board anything whatever to do with licensing osteopaths if the legislature did not really consider that they had something to do with the practice of medicine. The function of the Board is judicial throughout; it is not merely executive, and that it should be made so for the benefit of the osteopaths alone does not seem reasonable within the intent of the legislators. The judge, it appears to us, has made a strained interpretation of the statute; he ignores the very obvious implication of the act in putting the licensing of the osteopaths in the hands of the Medical Examining Board. His ruling, moreover, that the osteopathy act conferred no special privileges and was therefore not unconstitutional because the study of osteopathy is open to everyone, seems unreasonable as here applied. The legislature might enact that no one should vote who is not an osteopath and, according to this judge's construction, it would be constitutional, because everyone is privileged to adopt that alleged profession. He would "know of no legal reason why every citizen of Iowa can not bring himself within the provision of the act in question and thus secure the privilege provided thereby." He would probably find some precedent for this, but not in recent American law. His decision is, as far as it can be, a practical annulment of the medical laws of Iowa. It is to be hoped that it is not a final adjudication of the matter. If it is, it becomes the duty of the medical profession of Iowa to exercise their influence and see that legislation is secured that will not be possible to misconstrue in favor of ignorance. That they can do it, if they earnestly work for it, need not be questioned. But our inactivity in the past has led the lower grade of politicians—and among these we too often have to include the elective judges—to court the favor of blatant quacks and count for nothing the influence of educated physicians. It is time they were taught better.

#### MOSQUITOES AND MALARIA.

The mosquito has long been suspected of being a factor in the production of malaria, and during the past seven

1. Journ. Medical Research, 1902, January, 25-43.

years scientific methods have been employed by investigators in different malarious countries to determine whether this suspicion were true. The proof that the mosquito is an essential factor in the production and spread of malaria is now sufficiently conclusive to satisfy all biologists and physicians who have closely followed the publications upon the subject. The argument is still advanced by the laity, and even by some members of the medical profession that malaria can not be caused by mosquitoes because mosquitoes are abundant in many places where malaria does not prevail. Not all mosquitoes are carriers of malarial infection, but only those belonging to the genus anopheles. While it is true that anopheles are present in all places where malaria is rife, it is also a fact that anopheles may be and are present where there is no malaria. Anopheles are harmless unless they bite a person with malarial parasites in his blood. In the middle intestine of the infected mosquito sporoblastic forms of the parasite develop and from these there arise sporozoites which accumulate in the salivary glands and are again deposited in man's body when he is bitten by the insect. It follows then that both man infected with malaria, and anopheles are essential for the propagation of malaria. Celli, one of the accepted authorities upon the subject, says: "Down to the present time (1900) the hereditary transmission of malaria from mosquito to mosquito has not been demonstrated experimentally or morphologically." The inoculation of man through the proboscis of the mosquito at the time of the bite of the insect is the only way in which malaria has been proven to be naturally produced. In northern countries, where malaria is not endemic, anopheles have been found by various observers to be quite widely distributed, and they may become infected at any time if a person with malaria is introduced from without. This might occur if a soldier or other person who carries the malarial plasmodium in his blood, returns to his home after living in a malarious country. It is said that every case of malaria investigated by the Massachusetts State Board of Health during the past ten years has been traced to the presence in the neighborhood of Italian laborers. The mosquito must, therefore, be considered as only one of the essential factors in the spread of malaria, and in the effort to eradicate the disease the protection of the mosquito from infection from man is of almost equal importance with the protection of man from the bite of the infected insect.

## Medical News.

### CALIFORNIA.

**For failure to notify** the authorities that he had smallpox Dr. Malcolm K. McKenzie was removed from the Kern City Board of Health.

**Another Medical College.**—Physicians interested in starting a medical college in Oakland have secured \$3000 toward the building fund, and state that on April 1 work on the new building will be commenced.

**Club Practice.**—Sacramento Fraternal Hospital Association was incorporated, February 5. Its object is to give members of fraternal orders and their families, and any other who may wish to purchase stock, medical care at reasonable rates.

**New Hospital in Oakland.**—The Catholic Sisters of Providence have purchased for \$12,000 a site 350 by 221 feet whereon

they will erect a hospital which will afford clinical facilities to the Oakland College of Physicians and Surgeons.

**Expectoration Ordinance Enforced.**—More than fifty citizens of San Francisco were arrested for spitting on sidewalks in violation of the ordinance prohibiting expectoration in public places. Since the ordinance was passed in 1897, it has been enforced only once, and then the offender was fined \$5, and on a second offense was sent to jail for twenty-four hours.

### DISTRICT OF COLUMBIA.

**Marine-Hospital Appointment.**—Dr. Francis A. Ashford, son of the late Dr. F. A. Ashford, has been appointed resident physician at the marine-hospital at Chelsea, Mass.

**Senate Confirms Rixey's Appointment.**—The Senate has confirmed the nomination of Medical Inspector Presley M. Rixey, U. S. Navy, to be Chief of the Bureau of Medicine and Surgery in the Navy Department, with the rank of rear admiral. Surgeon-General Rixey succeeds Surgeon-General Van Keypen, just retired.

**Health of the District.**—The report of the health officer for the week ended February 8 shows the total number of deaths to have been 110, of which 59 were white and 51 colored; the death-rate per 1000 for the whites was 15.1 per cent. and for the colored 29.5. There were 4 cases of smallpox, 38 of diphtheria, and 27 of scarlet fever.

**Vacancies in Army Medical Service.**—Examination of applicants for appointment as assistant surgeons in the army will be resumed by the Medical Board in Washington, on April 7. The Board will remain in session until all the vacancies are filled. Full information concerning the nature and scope of the examination will be furnished on application to the Surgeon-General of the Army, Dr. George M. Sternberg. At present there are sixty-three vacancies in the medical corps.

**To Regulate Surgery in the Navy.**—The Secretary of the Navy has rendered an opinion on the question involving the rights of officers and men of the Navy in the matter of submission to surgical operations decided by the medical officers to be necessary for restoration to health and duty. The question arose from an inquiry by Surgeon O. D. Norton of the *Monadnock* for information as to the authority of medical officers in such cases. The Secretary rules as follows:

While the Department will not undertake to lay down as a general rule that a man must, particularly in cases involving risk of life or loss of limb, submit to a surgical operation, it can not, on the other hand, accept the opinion of the junior squadron commander on the Asiatic Station that it is optional with the man concerned whether or not he shall submit to such an operation in the course of medical treatment. By a judicious application of the principles set forth in an endorsement of the Bureau of Medicine and Surgery, friction in the cases of the character therein referred to will probably be avoided. In ordinary cases, when, in the opinion of the medical officer, after consultation, if advisable, with other surgeons available, it is deemed necessary, in order to restore a man to his capacity for the performance of his duties, that a minor surgical operation be made upon him, he can be required to undergo the same, under the penalty of punishment, as a sentence of court-martial, in the case of his refusal to submit thereto. If the particular case under consideration was of this character, disciplinary action would have been proper upon the report, made to the commanding officer of the *Monadnock*, by the surgeon, of the private's disobedience of orders.

### ILLINOIS.

**New Cottage Hospital Opened.**—The patients were transferred from the old into the new Cottage Hospital, Peoria, February 3.

**Julia F. Burnham Hospital,** Champaign, has received \$2000 bequeathed by the late Mary Ida Harris, to which her father, B. F. Harris, has added \$1000 as his personal contribution.

**Semi-Centenary of Practice.**—Dr. Clinton Helm, Rockford, who will complete his 50th year of practice this month, has been tendered a banquet by the Winnebago County Medical Society, February 25.

**Hospital for Incurable Insane.**—The State Hospital for the Incurable Insane at Bartonville, near Peoria, was formally opened February 10, and 100 patients from the Jacksonville hospital were installed in their new home.

### Chicago.

**The Bridewell Clinic.**—Dr. Heman Spalding suggests that a staff of internes be assigned to the Bridewell and that that institution be made use of as a place of clinical study. Medical classes should be taken out there and receive instruction through actual work.

**Chicago Eye, Ear, Nose and Throat College.**—The faculty held its annual meeting February 10. The following were

named as Board of Directors for the ensuing years: Drs. William A. Fisher, president; Adolphus G. Wipperfurth, vice-president; John R. Hoffman, secretary; Thomas Faith, and Harry W. Woodruff.

**Reforms at Dunning.**—The County Commissioners are planning many reforms at the county institutions, which include a reorganization and enlargement of the medical staff, relief of the overcrowded condition of the hospital for the insane, and eventually the erection of a series of cottages to replace the present building.

**Northwestern University Medical School.**—The faculty has set aside the week of June 16 as "alumni week." There will be general and special clinics of all kinds, private operations, ward visits, ward walks; men of international reputation will hold clinics at Mercy and Wesley Hospitals, and the alumni will be given special opportunity to see and study cases, for which they express a desire. It will be a week of concentrated post-graduate work. The social side of the week will consist of the banquet, small luncheons and dinners, receptions by the wives of the faculty, etc.

**New Mercy Hospital Amphitheater.**—The new clinical amphitheater in Mercy Hospital was dedicated, February 12, under the auspices of the Chicago Medical Society. Dr. John B. Deaver, of Philadelphia, made an eloquent address, eulogizing the hospital as a sign of the great strides by which science is advancing. The occasion was made further notable by the graduation of fourteen nurses from the training school. Dr. John H. Hollister presented the diplomas with words of wise counsel and hearty well-wishing. The introductory addresses by Prof. Robert D. Snepppard and Dr. Nathan S. Davis, Jr., were of a historical character. This fine amphitheater has been built at the expense of Northwestern University at a cost of \$25,000. It is beautifully finished and well equipped. The following morning the first clinic in the building was held by Dr. Deaver, who performed an operation upon the gall-bladder and an appendectomy.

#### INDIAN TERRITORY.

**Mayor Ejected from Territory.**—For refusing to comply with the law requiring physicians to receive certificates from the Choctaw Board of Health, before practicing medicine, Dr. W. A. Abbott, mayor of McAlester, has been removed from the territory and escorted to Oklahoma City by the chief of police.

**Health Ordinance.**—The city of Muskogee has passed an "ordinance to protect the inhabitants of the city from the evils of malignant, infectious and contagious diseases." The ordinance provides for compulsory vaccination, fumigation and disinfection of persons and premises and for the issuance of such rules as may be deemed necessary for the public safety.

**Medical Boards.**—The Choctaw Medical Board has notified physicians in the Going Snake, Tahlequah and Illinois districts to present themselves at Fort Gibson to be examined as to their professional qualifications. The Creek Medical Examining Board has ruled that graduates of reputable schools may obtain licenses by presenting their diplomas and paying a fee of \$5, but non-graduates must appear before the board and pay \$25 for examination.

#### IOWA.

**Certificate Revoked.**—The State Board of Health has revoked the license of Dr. Samuel C. Kirby, Grand Junction, after a three-days' trial, for incompetency. Dr. Kirby's fine for breaking quarantine last summer was noted in last week's Journal.

**The Board's Ultimatum.**—At a meeting of the State Board of Health, February 8, a resolution was adopted giving the local authorities of Des Moines 17 days to demonstrate their ability to deal with the smallpox situation. In the event of their failure successfully to do this, the board will convene in special session to take such action as may be thought best for the public health.

**Public Gatherings Prohibited.**—The city fathers of Des Moines have at last become aroused to the fact that the public health is in danger from smallpox, and has ordered all churches, theaters, lodges and other public gatherings prohibited during the prevalence of the disease. It has also ordered "that the city clerk notify all schools, and private parochial colleges, to prohibit the attendance of all pupils who are unable to show vaccination certificates from some reputable physician. Also that the managers of hotels, boarding-houses, business houses, or stores be requested to require employees to show vaccination certificates." Orders were given to employ 100 officers to estab-

lish a perfect quarantine over the 180 infected houses, and to employ as many physicians as the city physician desires to aid him in enforcing immediate general vaccination.

#### MARYLAND.

**Deaths in Baltimore.**—For the week ended February 15, the deaths were 232, the largest number being from pneumonia, namely 27.

**The Woman's Medical College,** Baltimore, celebrated its twentieth anniversary, February 22. Addresses were delivered by Drs. Louise Erich, W. Milton Lewis, W. F. Skillman, Henry Lee Smith, Henry P. Hynson and Francis M. Chisolm.

**Annapolis Hospital.**—A meeting was held at Annapolis, February 9, to consider the subject of establishing a hospital there. A board of lady managers was selected, and it was decided to erect a hospital to be called the "Emergency Hospital." A number of accidents have occurred which could be treated only after being taken by railroad to Baltimore.

**Detention Hospital.**—Health Commissioner Bosley has secured an old building on North Street, Baltimore, as a place of detention for smallpox cases until they can be sent to the Quarantine Hospital. The building is being comfortably equipped and furnished. The commissioner's action was made necessary by the mayor having forbidden suspects to be kept at the City Hall annex.

**Results of November Examination.**—The statistics of the last state medical examination, November 6 to 9, have been made public. There were 30 applicants, 2 of whom withdrew, of the other 28, 23 received an average of 75 and passed and 5 failed. The highest percentage, 94 1/3, was attained by a colored graduate of Rush Medical College. The 3 women who came up for examination, passed.

**Gift to Johns Hopkins University.**—The friends of the Johns Hopkins University have been gratified by the present to that institution by a number of public-spirited and wealthy citizens of Baltimore of a large tract of land in the northern suburbs sufficient for the growth and development of the University for a long time to come. Thither the university will be removed as soon as suitable buildings can be provided.

**Souvenir for Dr. Gilman.**—The alumni of Johns Hopkins University are preparing a unique gift for Ex-President Gilman, namely a handsomely bound book containing the autograph of every graduate of the institution. The silver jubilee of the University was held on February 21 and 22. A general reception was held on the evening of the first day, and the alumni held their meeting on the following evening. The laboratories and hospital were thrown open to visitors.

**Personal.**—Dr. Henry J. Berkley, clinical professor of psychiatry at the Johns Hopkins Medical School and author of a work upon that subject, has met with an accident which will probably cost him the sight of one eye. While working on an instrument in a shop in Baltimore, a piece of steel flew into the eye, injuring seriously the iris and cornea. Dr. S. S. Maynard has been elected physician of Montevue Hospital for the Insane at Frederick. Dr. William W. Goldsborough, a member of the legislature, will begin next month the publication of the *Caroline Sun*, at Ridgely, Caroline County.

**Maryland Woman's Quarter Club.**—As the result of the public meeting held at the Johns Hopkins University, January 28, and the statement of Dr. William Osler then made, that the neglect of the 10,000 consumptives in Baltimore is a disgrace to the city, an association has been formed, called the Maryland Woman's Quarter Club, whose purpose is the raising of funds to build a sanatorium for consumptives. The club was incorporated February 14, and as the name implies, 25-cent subscriptions will be asked for. A thousand subscription books have been printed and circulated, each containing 20 coupons, and these coupons are to be given in receipt for the subscriptions. Mrs. Robert Garrett has consented to act as treasurer for larger amounts, and everything indicates a great success. The purpose is to erect a state sanatorium in the mountains of Maryland, from which the greatest benefits may be expected.

#### MICHIGAN.

**Harper Hospital,** Detroit, receives \$10,000 bequeathed to it by the late Gen. John E. King.

**Health Appropriations.**—The health commission of Detroit has made its estimates for 1902-1903. It asks for \$38,638, or \$2893 more than it asked for last year. Of the amount asked for, \$5,000 is to be used in the conduct of a careful quarantine system.

**Battle Creek Sanatorium Burned.**—The Battle Creek Sanatorium, with its five-story hospital, annexes and conservatories, was burned just before daylight, February 18. More than 350 patients and 100 physicians, nurses and servants were sleeping in the building, but thanks to the presence of mind of the employees and the excellent fire escapes, only one death resulted. The property loss will be about \$500,000, on which there is about \$100,000 insurance.

**Comparative Morbidity.**—For January, compared with the preceding month, pneumonia and measles were more prevalent; and typhoid fever, intermittent fever, diphtheria and cerebrospinal meningitis were less prevalent. Compared with the average for January in the 10 preceding years, scarlet fever, smallpox and measles were more than usually prevalent; and influenza, consumption, intermittent fever, remittent fever, diphtheria and cerebrospinal meningitis were less than usually prevalent.

**Alger Not Entitled to Practice.**—In reply to the allegation of a homeopathic member of the State Medical Examining Board that Dr. Warren W. Alger was a competent physician and had failed to pass the board's examination by only 10 points, Dr. Beverly D. Harison, secretary of the board, states that W. W. Alger failed to pass two examinations, receiving respectively 60 and 53, the passing percentage being 75; that he is a graduate of the Independent Medical College, a diploma mill, Chicago, and that, not being legally registered under the medical act of 1883, his application for registration under the present act was refused.

**Mortality of Michigan.**—There were 2824 deaths returned to the Department of State for January, an increase of 54 deaths over the number returned for the preceding month. The death-rate was 13.5 per 1000 population, the same as for December. There were 442 deaths of infants under 1 year of age, 197 deaths of children aged 1 to 4 years, inclusive, and 910 deaths of persons aged 65 years and over. Important causes of death were as follows: tuberculosis, 200; typhoid fever, 45; diphtheria, 39; scarlet fever, 34; measles, 24; whooping cough, 19; pneumonia, 378; influenza, 64; cancer, 125; accidents and violence, 147. There was a slight increase in the number of deaths from pulmonary tuberculosis and pneumonia, and a considerable decrease in the mortality from diphtheria, as compared with the preceding month.

#### MISSOURI.

**Leper's Keeper Resigns.**—Dr. Louis Knapp, St. Louis, who five months ago renounced the world to become nurse and attendant to Dong Gong, the Chinese leper, has found isolation irksome, and has resigned. He will be replaced by a veteran quarantine nurse.

**Enlarge State Hospitals.**—Two wings to the main building at State Hospital for the Insane, No. 2, at St. Joseph, are to be erected at a cost of \$25,000. State Hospital, No. 3, at Nevada, is to have a new wing to the west of the present building, to cost also \$25,000.
